(4) Device and method for data compression/decompression.

An apparatus produces an encoded and compressed digital data stream from an original input digital data stream using a forward discrete wavelet transform and a tree encoding method. The input digital data stream may be a stream of video image data values in digital form. The apparatus is also capable of producing a decoded and decompressed digital data stream closely resembling the originally input digital data stream from an encoded and compressed digital data stream using a corresponding tree decoding method and a corresponding inverse discrete wavelet transform. A dual convolver is disclosed which performs both boundary and nonboundary filtering for forward transform discrete wavelet processing and which also performs filtering of corresponding inverse transform discrete wavelet processes. A portion of the dual convolver is also usable to filter an incoming stream of digital video image data values before forward discrete wavelet structures for processing. Methods and generating the addresses to read/write data values from/to memory as well as for reducing the total amount of memory necessary to store data values are also disclosed.

DESCRIPTION

30

35

5

This invention relates to a method and apparatus for compressing, decompressing, transmitting, and/or storing digitally encoded data. In particular, this invention relates to the compression and decompression of digital video image data.

An apparatus produces an encoded/compressed digital data stream from an original input digital data stream using a discrete wavelet transform and a tree encoding method. The apparatus is also capable of producing a decoded/decompressed digital data stream closely resembling the originally input digital data stream from an encoded/compressed digital data stream using a corresponding tree decoding method and a corresponding inverse discrete wavelet transform.

The apparatus comprises a discrete wavelet transform circuit which is capable of being configured to perform either a discrete wavelet transform or a corresponding inverse discrete wavelet transform. The discrete wavelet transform circuit comprises an address generator which generates the appropriate addresses to access data values stored in memory. Methods and structures for reducing the total amount of memory necessary to store data values and for taking advantage of various types of memory devices including dynamic random access memory (DRAM) devices are disclosed. A convolver circuit of the discrete wavelet transform circuit performs both boundary and non-boundary filtering for the forward discrete wavelet transform and performs start, odd, even and end reconstruction filtering for the inverse discrete wavelet transform. The convolver may serve the dual functions of 1) reducing the number of image data values before subsequent forward discrete wavelet transforming, and 2) operating on the reduced number of image data values to perform the forward discrete wavelet transform.

The apparatus also comprises a tree processor/ encoder-decoder circuit which is configurable in an encoder mode or in a decoder mode. In the encoder mode, the tree processor/encoder-decoder circuit generates addresses to traverse trees of data values of a sub-band decomposition, generates tokens, and quantizes and Huffman encodes selected transformed data values stored in memory. In the decoder mode, the tree processor/decoder-encoder circuit receives Huffman encoded data values and tokens, Huffman decodes and inverse quantizes the encoded data values, recreates trees of transformed data values from the tokens and data values, and stores the recreated trees of data values in memory.

The apparatus is useful in, but not limited to, the fields of video data storage, video data transmission, television, video telephony, computer networking, and other fields of digital electronics in which efficient storage and/or transmission and/or retrieval of digitally encoded data is needed. The apparatus facilitates the efficient and inexpensive compression and storage of video and/or audio on compact laser discs (commonly known as CDs) as well as the efficient and inexpensive storage of video and/or audio on digital video tapes (commonly known as VCR or "video cassette recorder" tapes). Similarly, the invention facilitates the efficient

and inexpensive retrieval and decompression of video and/or audio from digital data storage media including CDs and VCR tapes.

The invention is further described below, by way of example, with reference to the accompanying drawings, in which:

Figure 47 illustrates a time line of the sequence of operations of the circuit illustrated in Figure 46.

Figure 1 illustrates a printed circuit expansion board 100 which is insertable into a card slot of a personal computer. Printed circuit board 100 may be used to demonstrate features in accordance with various aspects of the present invention. Printed circuit board 100 receives an analog video signal 101 from an external video source 104 (such as a CD player), converts information in the analog video signal into data in digital form, transforms and compresses the data, and outputs compressed data onto a computer data bus 106 (such as an ISA/NUBUS parallel bus of an IBM PC or IBM PC compatible personal computer). While performing this compression function, the board 100 can also output a video signal which is retrievable from the compressed data. This video signal can be displayed on an external monitor 108. This allows the user to check visually the quality of images which will be retrievable later from the compressed data while the compressed data is being generated. Board 100 can also read previously compressed video data from data bus 106 of the personal computer, decompress and inverse-transform that data into an analog video signal, and output this analog video signal to the external monitor 108 for display.

Board 100 comprises an analog-to-digital video decoder 110, a video encoder/decoder integrated circuit chip 112, two static random access memory (SRAM) memory units 114 and 116, a display driver 118, and a first-in-first-out memory 120. Analog-to-digital (A/D) video decoder 110 converts incoming analog video signal 101 into a digital format. Video encoder/decoder chip 112 receives the video signal in the digital format and performs a discrete wavelet transform (DWT) function, and then a tree processing function, and then a Huffman encoding function to produce a corresponding compressed digital data stream. Memory unit 116 stores "new" and "old" DWT-transformed video frames.

Video encoder/decoder chip 112 comprises a discrete wavelet transform circuit 122 and a tree proces-

sor/ encoder-decoder circuit 124. The discrete wavelet transform circuit 122 performs either a forward discrete wavelet transformation, depending on whether the chip 112 is configured to compress video data or to decompress compressed video data. Similarly, the tree processor/encoder-decoder circuit 124 either encodes wavelet-transformed images into a compressed data stream or decodes a compressed data stream into decompressed images in wavelet transform form, depending on whether the chip 112 is configured to compress or to decompress video data. Video encoder/decoder chip 112 is also coupled to computer bus 106 via a download register bus 128 so that the discrete wavelet transform circuit 122 and the tree processor/encoder-decoder circuit 124 can receive control values (such as a value indicative of image size) from ISA bus 106. The control values are used to control the transformation, tree processing, and encoding/decoding operations. FIFO buffer 120 buffers data flow between the video encoder/decoder chip 112 and the data bus 106. Memory unit 114 stores a video frame in uncompressed digital video format. Display driver chip 118 converts digital video data from either decoder 110 or from memory unit 114 into an analog video signal which can be displayed on external monitor 108.

Figure 2 is a block diagram of analog/digital video decoder 110. Analog/digital video decoder 110 converts the analog video input signal 101 into one 8-bit digital image data output signal 202 and two digital video SYNC output signals 201. The 8-bit digital image output signal 202 contains the pixel luminance values, Y, time multiplexed with the pixel chrominance values, U and V. The video SYNC output signals 201 comprise a horizontal synchronization signal and a vertical synchronization signal.

20

30

Figures 3A-C illustrate a 4:1:1 luminance-chrominance format (Y:U:V) used by board 100. Because the human eye is less sensitive to chrominance variations than to luminance variations, chrominance values are subsampled such that each pixel shares an 8-bit chrominance value U and an 8-bit chrominance value V with three of its neighboring pixels. The four pixels in the upper-left hand corner of the image, for example, are represented by $\{Y_{00}, U_{00}, V_{00}\}$, $\{Y_{01}, U_{00}, V_{00}\}$, $\{Y_{10}, U_{00}, V_{00}\}$, and $\{Y_{11}, U_{00}, V_{00}\}$. The next four pixels to the right are represented by $\{Y_{02}, U_{01}, V_{01}, \{Y_{02}, U_{01}, V_{01}\}, \{Y_{12}, U_{01}, V_{01}\}, and <math>\{Y_{13}, U_{01}, V_{01}\}$. AD video decoder 110 serially outputs all the 8-bit Y-luminance values of a frame, followed by all the 8-bit U-chrominance values of the frame. The Y, U and V values for a frame are output every 1/30 of a second. A/D video decoder 110 outputs values in raster-scan format so that a row of pixel values Y_{00} , Y_{01} , Y_{02} ... is output followed by a second row of pixel values Y_{10} , Y_{11} , Y_{12} ... and so forth until all the values of the frame of Figure 3A are output. The values of Figure 3B are then output row by row and then the values of Figure 3C are output row by row. In this 4:1:1 format, each of the U and V components of the image contains one quarter of the number of data values contained in the Y component.

Figure 4 is a diagram of a timeline of the output of A/D video decoder 110. The bit rate of the decoder output is equal to 30 frames/sec x 12 bits/pixel. For a 640 x 400 pixel image, for example, the data rate is approximately 110 x 10⁸ bits/second. A/D video decoder 110 also detects the horizontal and vertical synchronization signals in the incoming analog video input signal 102 and produces corresponding digital video SYNC output signals 201 to the video encoder/decoder chip 112.

The video encoder/decoder integrated circuit chip 112 has two modes of operation. It can either transform and compress ("encode") a video data stream into a compressed data stream or it can inverse transform and decompress ("decode") a compressed data stream into a video data stream. In the compression mode, the digital image data 202 and the synchronization signals 201 are passed from the A/D video decoder 110 to the discrete wavelet transform circuit 122 inside the video encoder/decoder chip 112. The discrete wavelet transform circuit 122 performs a forward discrete wavelet transform operation on the image data and stores the resulting wavelet-transformed image data in the "new" portion of memory unit 116. At various times during this forward transform operation, the "new" portion of memory unit 116 stores intermediate wavelet transform results, such that certain of the memory locations of memory unit 116 are read and overwritten a number of times. The number of times the memory locations are overwritten corresponds to the number of octaves in the wavelet transform. After the image data has been converted into a sub-band decomposition of wavelet-transformed image data, the tree processor/ encoder-decoder circuit 124 of encoder/decoder chip 112 reads wavelet-transformed image data of the sub-band decomposition from the "new" portion of memory 116, processes it, and outputs onto lines 130 a compressed ("encoded") digital data stream to FIFO buffer 120. During this tree processing and encoding operation, the tree processor/encoder-decoder circuit 124 also generates a quantized version of the encoded first frame and stores that quantized version in the "old" portion of memory unit 116. The quantized version of the encoded first frame is used as a reference when a second frame of wavelet-transformed image data from the "new" portion of memory unit 116 is subsequently encoded and output to bus 106. While the second frame is encoded and output to bus 106, a quantized version of the encoded second frame is written to the "old" portion of memory unit 116. Similarly, the quantized version of the encoded second frame in the "old" portion of memory unit 116 is later used as a reference for encoding a third frame of image data.

is read from FIFO 120 into tree processor/encoder-decoder circuit 124 of the video encoder/decoder chip 112. The tree processor/encoder-decoder circuit 124 decodes the compressed data into decompressed wavelettransformed image data and then stores the decompressed wavelet-transformed image data into the "old" portion of memory unit 116. During this operation, the "new" portion of memory unit 116 is not used. Rather, the tree processor/encoder-decoder circuit 124 reads the previous frame stored in the "old" portion of memory unit 116 and modifies it with information from the data stream received from FIFO 120 in order to generate the next frame. The next frame is written over the previous frame in the same "old" portion of the memory unit 118. Once the decoded wavelet-transformed data of a frame of image data is present in the "old" portion of memory unit 116, the discrete wavelet transform circuit 122 accesses memory unit 116 and performs an inverse discrete wavelet transform operation on the frame of image data. For each successive octave of the inverse transform, certain of the memory locations in the "old" portion of memory unit 116 are read and overwritten. The number of times the locations are overwritten corresponds to the number of octaves in the wavelet transform. On the final octave of the inverse transform which converts the image data from octave-0 transform domain into standard Image domain, the discrete wavelet transform circuit 122 writes the resulting decompressed and inverse-transformed image data into memory unit 114. The decompressed and inverse-transformed image data may also be output to the video display driver 118 and displayed on monitor 108.

Figure 5 is a block diagram of the discrete wavelet transform circuit 122 of video encoder/decoder chip 112. The discrete wavelet transform circuit 122 shown enclosed by a dashed line comprises a row convolver block CONV_ROW 502, a column convolver block CONV_COL 504, a control block 508, a DWT address generator block 508, a REGISTERS block 538, and three multiplexers, mux1 510, mux2 512, and mux3 514. In order to transform a frame of digital video image data received from A/D video decoder 110 into the wavelet transform domain, a forward two dimensional discrete wavelet transform is performed. Similarly, in order to return the wavelet transform digital data values of the frame into a digital video output suitable for displaying on a monitor such as 108, an inverse two dimensional discrete wavelet transform is performed. In the presently described embodiment of the present invention, four coefficient quasi-Daubechies digital filters are used as set forth in the copending Patent Cooperation Treaty (PCT) application filed March 30, 1994 entitled "Data Compression and Decompression".

The discrete wavelet transform circuit 122 shown in Figure 5 performs a forward discrete wavelet transform as follows. First, a stream of 8-bit digital video image data values is supplied, one value at a time, to the discrete wavelet transform circuit 122 via eight leads 516. The digital video image data values are coupled through multiplexer mux1 510 to the input leads 518 of the row convolver CONV_ROW block 502. The output leads 520 of CONV_ROW block 502 are coupled through multiplexer mux2 512 to input leads 522 of the CONV_COL block 504. The output leads 524 of CONV_COL 504 block are coupled to data leads 526 of memory unit 116 through multiplexer mux3 so that the data values output from CONV_COL block 504 can be written to the "new" portion of frame memory unit 116. The writing of the "new" portion of memory unit 116 completes the first pass, or octave, of the forward wavelet transform. To perform the next pass, or octave, of the forward wavelet transform, low pass component data values of the octave 0 transformed data values are read from memory unit 116 and are supplied to input leads 518 of CONV_ROW block 502 via input leads 526, lines 528 and multiplexer mux1 510. The flow of data proceeds through row convolver CONV_ROW block 502 and through column convolver CONV_COL block 504 with the data output from CONV_COL block 504 again being written into memory unit 116 through multiplexer mux3 514 and leads 526. Control block 506 provides control signals to mux1 510, mux2 512, mux3 514, CONV_ROW block 502, CONV_COL block 504, DWT address generator block 508, and memory unit 116 during this process. This process is repeated for each successive octave of the forward transform. The data values read from memory unit 116 for the next octave of the transform are the low pass values written to the memory unit 116 on the previous octave of the transform.

The operations performed to carry out the inverse discrete wavelet transform proceed in an order substantially opposite the operations performed to carry out the forward discrete wavelet transform. The frame of image data begins in the transformed state in memory unit 116. For example, if the highest octave in the forward transform (OCT) is octave 1, then transformed data values are read from memory unit 116 and are supplied to the input leads 522 of the CONV_COL block 504 via leads 526, lines 528 and multiplexer mux2 512. The data values output from CONV_COL block 504 are then supplied to the input leads 518 of CONV_ROW block 502 via lines 525 and multiplexer mux1 510. The data values output from CONV_ROW block 502 and present on output leads 520 are written into memory unit 116 via lines 532, multiplexer mux3 514 and leads 526. The next octave, octave 0, of the inverse transform proceeds in similar fashion except that the data values output by CONV_ROW block 502 are the fully inverse-transformed video data which are sent to memory unit 114 via lines 516 rather than to memory unit 116. Control block 506 provides control signals to multiplexer mux1 510, multiplexer mux2 512, multiplexer mux3 514, CONV_ROW block 502, CONV_COL block 504, DWT address generator block 508, memory unit 116, and memory unit 114 during this process.

45

In both forward wavelet transform and inverse wavelet transform operations, the control block 506 is timed by the external video sync signals 201 received from A/D video decoder 110. Control block 506 uses these sync signals as well as register input values ximage, yimage, and direction to generate the appropriate control signals mentioned above. Control block 506 is coupled to: multiplexer mux1 510 via control leads 550, multiplexer mux2 512 via control leads 552, multiplexer mux3 via control leads 554, CONV_ROW block 502 via control leads 546, CONV_COL block 504 via control leads 548, DWT address generator block 508 via control leads 534, 544, and 556, memory unit 116 via control leads 2108, and memory unit 114 via control leads 2106.

As shown in Figure 5, multiplexer mux1 510 couples one of the following three sets of input signals to input leads 518 of CONV_ROW block 502, depending on the value of control signals on leads 550 supplied from CONTROL block 506: digital video input data values received on lines 516 from A/D video decoder 110, data values from memory unit 116 or data values from multiplexer mux3 514 received on lines 528, or data values from CONV_COL block 504 received on lines 525. Multiplexer mux2 512 couples either the data values being output from row convolver CONV_ROW block 502 or the data values being output from multiplexer mux3 514 received on lines 528 to Input leads 522 of CONV_COL block 504, depending on the value of control signals on lead 552 generated by CONTROL block 506. Multiplexer mux3 514 passes either the data values being output from CONV_ROW 502 received on lines 532 or the data values being output from CONV_COL 504 onto lines 523 and leads 526, depending on control signals generated by CONTROL block 506. Blocks CONV_ROW 502, CONV_COL 504, CONTROL 506, DWT address generator 508, and REGISTERS 536 of Figure 5 are described below in detail in connection with a forward transformation of a matrix of digital image data values. Lines 516, 532, 528 and 525 as well as input and output leads 518, 520, 522, 524 and 526 are each sixteen bit parallel lines and leads.

10

20

25

Figure 6 is a block diagram of the row convolver CONV_ROW block 502. Figure 7 is a block diagram of the column convolver CONV_COL block 504. Figure 21 is a block diagram of the CONTROL block 506 of Figure 5. Figure 30 is a block diagram of the DWT address generator block 508 of Figure 5.

As illustrated in Figure 6, CONV_ROW block 502 comprises a wavelet transform multiplier circuit 602, a row wavelet transform circuit 604, a delay element 808, a multiplexer MUX 608, and a variable shift register 610. To perform a forward discrete wavelet transform, digital video values are supplied one-by-one to the discrete wavelet transform circuit 122 of the video encoder/decoder chip 112 illustrated in Figure 1. In one embodiment in accordance with the present invention, the digital video values are in the form of a stream of values comprising 8-bit Y (luminance) values, followed by 8-bit U (chrominance) values, followed by 8-bit V (chrominance) values. The digital video data values are input in "raster scan" form. For clarity and ease of explanation, a forward discrete wavelet transform of an eight-by-eight matrix of luminance values Y as described is represented by Table 1. Extending the matrix of Y values to a larger size is straightforward. If the matrix of Y values is an eight-by-eight matrix, then the subsequent U and V matrices will each be four-by-four matrices.

D ₀₀	D ₀₁	D ₀₂				•	_

Table 1.

The order of the Y values supplied to the discrete wavelet transform circuit 122 is D_{00} , D_{01} , ... D_{07} in the first row, then D_{10} , D_{11} , ... D_{17} in the second row, and so forth row by row through the values in Table 1. Multiplexer 510 in Figure 5 is controlled by control block 506 to couple this stream of data values to the row convolver CONV_ROW block 502. The row convolver CONV_ROW block 502 performs a row convolution of the row data values D_{00} , D_{01} , D_{02} , ... D_{07} with a high pass four coefficient quasi-Daubechies digital filter D_{01} where D_{02} in the coefficient quasi-Daubechies digital filter D_{01} where D_{02} in the coefficients D_{01} and a low pass four coefficients D_{01} and D_{02} in the coefficients D_{01} and D_{02} are related to a four coefficient Daubechies wavelet as described in the copending Patent Cooperation Treaty (PCT) application filed March 30, 1994, entitled "Data Compression and Decompression".

The operation of CONV_ROW block 502 on the data values of Table 1 is explained with reference to Figures 6, 8, 9, 10 and 11. Figure 8 is a detailed block diagram of the wavelet transform multiplier circuit 602 of the CONV_ROW block. Figure 9 is a detailed block diagram of the row wavelet transform circuit 604 of the CONV_ROW block. Figure 10 shows a sequence of control signals supplied by the control block 506 of Figure 5 to the row wavelet transform circuit 604 of Figure 9. This sequence of control signals effects a forward one dimensional wavelet transform on the rows of the matrix Table 1. The wavelet transform multiplier circuit 602 of Figure 8 comprises combinatorial logic which multiplies each successive input data value x by various scaled combinations of coefficients 32a, 32b, 32c, and 32d. This combinational-logic block comprises shift registers 802, 804, 806, and 808 which shift the multibit binary input data value x to the left by 1, 2, 3, and 4 bits, respectively. Various combinations of these shifted values, as well as the input value x itself, are supplied to multibit adders 810, 812, 814, 816, and 818. The data outputs 32dx, 32(c-d)x, 32cx, 32ax, 32(a+b)x, 32bx, and 32(c+d)x are therefore available to the row wavelet transform circuit 604 on separate sets of leads as shown in detail in Figures 6 and 9.

The row wavelet transform circuit 604 of Figure 9 comprises sets of multiplexers, adders, and delay elements. Multiplexer mux1 902, multiplexer mux2 904, and multiplexer mux3 906 pass selected ones of the data outputs of the wavelet transform multiplier circuit 602 of Figure 8 as determined by control signals on leads 546 from CONTROL block 506 of Figure 5. These control signals on leads 546 are designated muxsel(1), muxsel(2), and muxsel(3) on Figure 9. The remainder of the control signals on leads 546 supplied from CONTROL block 506 to the row wavelet transform circuit 604 comprise andsel(1), andsel(2), andsel(3), andsel(4), addsel(4), muxandsel(1), muxandsel(2), muxandsel(3), centermuxsel(1) and centermuxsel(2).

20

30

35

40

45

Figure 10 shows values of the control signals at different times during a row convolution of the forward transform. For example, at time t=0, the control input signal to multiplexer mux2 904, muxsel(2), is equal to 2. Multiplexer mux2 904 therefore couples its second input leads carrying the value 32(a+b)x to its output leads. Each of multiplexers 908, 910, 912, and 914 either passes the data value on its input leads, or passes a zero, depending on the value of its control signal. Control signals andsel(1) through andsel(4) are supplied to select input leads of multiplexers 908, 910, 912, and 914, respectively. Multiplexers 916, 918, and 920 have similar functionality. The outputs of multiplexers 918, 918, and 920 depend on the values of control signals muxand-sel(1) through muxandsel(3), respectively. Multiplexers 922 and 924 pass either the value on their "left" input leads or the value on their "right" input leads, as determined by control select inputs centermuxsel(1) and centermuxsel(2), respectively. Adder/subtractors 926, 928, 930, and 932 either pass the sum or the difference of the values on their left and right input leads, depending on the values of the control signals addsel(1) through addsel(4), respectively. Elements 934, 936, 938, and 940 are one-cycle delay elements which output the data values that were at their respective input leads during the previous time period.

Figure 11 is a diagram of a data flow through the row convolver CONV_ROW 502 during a forward transform operation on the data values of Table 1 when the control signals 546 controlling the row convolver CONV_ROW 502 are as shown in Figure 10. At the left hand edge of the matrix of the data values of Table 1, start forward low pass and start forward high pass filters G_s and H_s are applied in accordance with equations 22 and 24 of copending Patent Cooperation Treaty (PCT) application filed March 30, 1994, entitled "Data Compression and Decompression" as follows:

$$32H_{00} = 32((a + b)D_{00} + cD_{01} - dD_{02})$$

 $32G_{00} = 32((c + d)D_{00} - bD_{01} + aD_{02})$

The row wavelet transform circuit of Figure 9 begins applying these start forward low and high pass filters when the control signals for this circuit assume the values at time t=0 as illustrated in Figure 10.

At time t=0, muxsel(2) has a value of 2. Multiplexer mux2 904 therefore outputs the value $32(a+b)D_{00}$ onto its output leads. Muxsel(3) has a value of 3 so multiplexer mux3 906 outputs the value $32(c+d)D_{00}$ into its output leads. Because the control signals andsel(2) and andsel(3) cause multiplexers 910 and 912 to output zeros at t=0 as shown in Figure 10, the output leads of adder/subtractor blocks 928 and 930 carry the values $32(a+b)D_{00}$ and $32(c+d)D_{00}$, respectively, as shown in Figure 11. These values are supplied to the input leads of delay elements 936 and 938. Delay elements 938 and 938 in the case of the row transform are one time unit delay elements. The control signals centermuxsel(1) and centermuxsel(2) have no effect at t=0, because control signals andsel(3) cause multipliers 910 and 912 to output zeros.

At time t=1, input data value x is the data value D_{01} . Control signal muxsel(2) is set to 1 so that multiplexer mux2 904 outputs the value $32bD_{01}$. The select signal centermuxsel(1) for adder/subtractor block 922 is set to pass the value on its right input leads. The value $32(c+d)D_{00}$, the output of adder/subtractor block 930 at t=0, is therefore passed through multiplexer mux4 922 due to the one time unit delay of delay element 938. The control signal andsel(2) is set to pass, so the two values supplied to the adder/subtractor block 928 are $32(c+d)D_{00}$ and $32bD_{01}$. Because the control signal addsel(2) is set to subtract, the value output by adder/sub-

tractor block 928 is $32\{(c+d)D_{00}-bD_{01}\}$ as shown in Figure 11. Similarly, with the values of control signals centermuxsel(2), andsel(3), muxsel(3), muxandsel(2)-, and addsel(3) given in Figure 10, the value output by adder/subtractor block 930 is $32\{(a+b)D_{00}+cD_{01}\}$ as shown in Figure 11.

At time t=2, input data value x is data value D_{02} . The control signals and sel(1), muxsel(1), and muxandsel(1) are set so that the inputs to adder/subtractor block 926 are $32aD_{02}$ and $32\{(c+d)D_{00}-bD_{01}\}$. The value $32\{(c+d)D_{00}-bD_{01}\}$ was the previous output from adder/subtractor block 928. Because control signal addsel(1) is set to add as shown in Figure 10, the output of block 926 is $32\{(c+d)D_{00}-bD_{01}+aD_{02}\}$ as shown in Figure 11. Similarly, with the value of control signals addsel(4), and sel(4) and muxandsel(3), the value output by adder/subtractor block 932 is $32\{(a+b)D_{00}+cD_{01}-dD_{02}\}$ as shown in Figure 11.

10

20

25

30

40

55

As illustrated in Figure 10, output leads OUT2 (which are the output leads of delay element 940) carry a value of 32H₀₀ at time t=3. The value 32{(a+b)D₀₀-bD₀₁+aD₀₂} is equal to 32H₀₀ because 32H₀₀=32{(a+b)D₀₀+cD₀₁-dD₀₂} as set forth above. Similarly, output leads OUT1 (which are the output leads of delay element 934) carry a value of 32G₀₀ at t=3 because output leads of block 926 have a value of 32{(c+d)D₀₀-bD₀₁+aD₀₂) one time period earlier. Because 32H₀₀ precedes 32G₀₀ in the data stream comprising the high and low pass components in a one-dimensional row convolution, delay element 606 is provided in the CONV_ROW row convolver of Figure 6 to delay 32G₀₀ so that 32G₀₀ follows 32H₀₀ on the leads which are input to the multiplexer 608. Multiplexer 608 selects between the left and right inputs shown in Figure 6 as dictated by the value mux_608, which is provided on one of the control leads 546 from control block 506. The signal mux_608 is timed such that the value 32H₀₀ precedes the value 32G₀₀ on the output leads of multiplexer 608.

The output leads of multiplexer 608 are coupled to a variable shift register 610 as shown in Figure 6. The function of the variable shift register 610 is to normalize the data values output from the CONV_ROW block by shifting the value output by multiplexer 608 to the right by m_row bits. In this instance, for example, it is desirable to divide the value output of multiplexer 608 by 32 to produce the normalized values H₀₀ and G₀₀. To accomplish this, the value m_row provided by control block 506 via one of the control leads 546 is set to 5. The general rule followed by the control block 506 of the discrete wavelet transform circuit is to: (1) set m_row equal to 5 to divide by 32 during the forward transform, (2) set m_row equal to 4 to divide by 16 during the middle of a row during an inverse transform, and (3) set m_row equal to 3 to divide by 8 when generating a start or end value of a row during the inverse transform. In the example being described, the start values of a transformed row during a forward transform are being generated, so m_row is appropriately set equal to 5.

As illustrated in Figure 10, the centermuxsel(1) and centermuxsel(2) control signals alternate such that the values on the right and the left input leads of multiplexers 922 and 924 are passed to their respective output leads for each successive data value convolved. This reverses data flow through the adder/subtractor blocks 928 and 930 in alternating time periods. In time period t=0, for example, Figure 11 indicates that the value $32aD_{01}$ in the column designated "Output of Block 926" in time period t=1 is added to $32bD_{02}$ to form the value $32\{aD_{01} + bD_{02}\}$ in the column designated "Output of Block 930" is added to $32bD_{03}$ to form the value $32\{dD_{01} + cD_{02}\}$ in the column designated "Output of Block 930" is added to $32bD_{03}$ to form the value $32\{dD_{01} + cD_{02}\}$ in the column designated "Output of Block 928".

Accordingly, in time period t=2, the two values supplied to block 928 are $32bD_{02}$ and the previous output from block 926, $32bD_{01}$. Because addsel(2) is set to add as shown in Figure 10, the value output by block 928 is $32(aD_{01} + bD_{02})$.

Similarly, the output of block 930 is $32(dD_{01} + cD_{02})$. In this way it can be seen the sequence of control signals in Figure 10 causes the circuit of Figure 9 to execute the data flow in Figure 11 to generate, after passage through multiplexer mux 608 and shift register 610 with m_row set equal to 5, the low and high pass non-boundary components H_{01} , G_{01} , H_{02} , and G_{02} . To implement the end forward low and high pass filters beginning at t=7 when the last data value of the first row of Table 1, D_{07} , is input to the row convolver, the control signal muxsel(2) is set to 3, so that $32(b-a)D_{07}$ is passed to block 928. Control signal muxsel(3) is set to 4, so that $32(c-d)D_{07}$ is passed to block 930. Control signal addsel(2) is set to subtract and control signal addsel(3) is set to add. Accordingly, the output of adder/subtractor 928 is $32(dD_{05}+cD_{06}-(b-a)D_{07})$. Similarly, the output of adder/subtractor 930 is $32(aD_{05}+bD_{06}+(c-d)D_{07})$.

As shown in Figure 11, these values are output from blocks 926 and 932 at the next time period when t=8 by setting muxandsel(1) and muxandsel(3) to be both zero so that adder/subtractor blocks 926 and 932 simply pass the values unchanged. Delay elements 934 and 940 cause the values $32G_{03}$ and $32H_{03}$ to be output from output leads OUT1 and OUT2 at time t=9. Multiplexer 608, as shown in Figure 6, selects between the output of delay unit 606 and the OUT2 output as dictated by CONTROL block 508 of Figure 5. Shift register 610 then normalizes the output as described previously, with m_row set equal to 5 for the end of the row. The resulting values G_{03} and H_{03} are the values output by the end low pass and end high pass forward transform digital filters in accordance with equations 28 and 28 of copending Patent Cooperation Treaty (PCT) application filed March

30, 1994, entitled "Data Compression and Decompression". Thus, a three coefficient start forward transform low pass filter and a three coefficient start forward transform high pass filter have generated the values H_{00} and G_{00} . A four coefficient quasi-Daubecheis low pass forward transform filter and a four coefficient quasi-Daubecheis high pass forward transform filter have generated the values H_{01} ... G_{02} . A three coefficient end forward transform low pass filter and a three coefficient end forward transform high pass filter have generated the values H_{03} and G_{03} .

The same sequence is repeated for each of the rows of the matrix in Table 1. In this way, for each two data values input there is one high pass (G) data value generated and there is one low pass (H) data value generated. The resulting output data values of CONV_ROW block 502 are shown in Figure 12.

As illustrated in Figure 5, the values output from row convolver CONV_ROW block 502 are passed to the column convolver CONV_COL block 504 in order to perform column convolution using the same filters in accordance with the method set forth in copending Patent Cooperation Treaty (PCT) application filed March 30, 1994, entitled "Data Compression and Decompression".

10

35

45

Figure 7 is a block diagram of the column convolver CONV_COL block 504 of Figure 5. The CONV_COL block 504 comprises a wavelet transform multiplier circuit 702, a column wavelet transform circuit 704, a multiplexer 708, and a variable shift register 710. In general, the overall operation of the circuit shown in Figure 7 is similar to the overall operation of the circuit shown in Figure 6. The wavelet transform multiplier circuit 702 of the column convolver is identical to the wavelet transform multiplier circuit 602 of Figure 6. The dashed line in Figure 8. Therefore, is designated with both reference numerals 602 and 702.

Figure 13 is a detailed block diagram of the column wavelet transform circuit 704 of Figure 7 of the column convolver. The CONV_COL block 504, as shown in Figure 13, is similar to the CONV_ROW block 502, except that the unitary delay elements 934, 936, 938, and 940 of the CONV_ROW block 502 are replaced by "line delay" blocks 1334, 1336, 1338, and 1340, respectively. The line delay blocks represent a time delay of one row which, in the case of the matrix of the presently described example, is eight time units. In some embodiments in accordance with the present invention, the line delays are realized using random access memory (RAM).

To perform a column convolution on the values of the matrix of Figure 12, the first three values H_{00} , H_{10} , of the first column are processed to generate, after a bit shift in shift register 710 of Figure 7, low and high pass values HH_{00} and HG_{00} of Figure 18. The first three values G_{00} , G_{10} , G_{20} of the second column of the matrix of Figure 12 are then processed to likewise produce GH_{00} and GG_{00} , and so on, to produce the top two rows of values of the matrix of Figure 16. Three values in each column are processed because the start low and high pass filters are three coefficient filters rather than four coefficient filters.

Figure 14 is a diagram illustrating control signals which control the column convolver during the forward transform of the data values of Figure 12. Figure 15 is a diagram illustrating data flow through the column convolver. Corresponding pairs of data values are output from line delays 1334 and 1340 of the column wavelet transform circuit 704. For this reason, the low pass filter output values are supplied from the output leads of the adder/subtractor block 1332 at the input leads of line delay 1340 rather than from the output leads of the line delay 1340 so that a single transformed data value is output from the column wavelet transform circuit in each time period. In Figure 14, output data values 32HH₀₀ ... 32GH₀₃ are output during time periods t=16 to t=23 whereas output data values 32HG₀₀ ... 32GG₀₃ are output during time periods t=24 to t=31, one line delay later. After being passed through multiplexer 708 and variable shift register 710 of Figure 7, the column convolved data values HH₀₀ ... GH₀₃ and HG₀₀ ... GG₀₃ are written to memory unit 116 under the control of the address generator. After all the data values of Figure 16 are written to memory unit 116, an octave 0 sub-band decomposition exists in memory unit 116.

To perform the next octave of decomposition, only the low pass component HH values in memory unit 116 are processed. The HH values are read from memory unit 116 and passed through the CONV_ROW block 502 and CONV_COL block 504 as before, except that the control signals for control block 506 are modified to reflect the smaller matrix of data values being processed. The line delay in the CONV_COL block 504 is also shortened to four time units because there are now only four low pass component HH values per row. The control signals to accomplish the octave 1 forward row transform on the data values in Figure 16 are shown in Figure 17. The corresponding data flow for the octave 1 forward row transform is shown in Figure 18. Likewise, the control signals to accomplish the octave 1 forward column transform are shown in Figure 19, and the corresponding data flow for the octave 1 forward column transform is shown in Figure 20.

The resulting HHHH, HHHG, HHGH, and HHGG data values output from the column convolver CONV_COL block 504 are sent to memory unit 116 to overwrite only the locations in memory unit 116 storing corresponding HH data values as explained in connection with Figures 17 and 18 of copending Patent Cooperation Treaty (PCT) application filed March 30, 1994, entitled "Data Compression and Decompression". The result is an octave 1 sub-band decomposition stored in memory unit 116. This process can be performed on

large matrices of data values to generate sub-band decompositions having as many octaves as required. For ease of explanation and illustration, control inputs and dataflow diagrams are not shown for the presently described example for octaves higher than octave 1. However, control inputs and dataflows for octaves 2 and above can be constructed given the method described in copending Patent Cooperation Treaty (PCT) application filed March 30, 1994, entitled "Data Compression and Decompression" along with the octave 0 and octave 1 implementation of that method described above.

Figure 21 illustrates a block diagram of one possible embodiment of control block 506 of Figure 5. Control block 506 comprises a counter 2102 and a combinatorial logic block 2104. The control signals for the forward and inverse discrete wavelet transform operations, as shown in Figures 10, 14, 17, 19, 22, 24, 26, and 28, are output onto the output leads of the combinatorial logic block 2104. The input signals to the control block 506 comprise the sync leads 201 which are coupled to A/D video decoder 110, the direction lead 538 which is coupled to REGISTERS block 536, and the image size leads 540 and 542 which are also coupled to REGISTERS block 536. The values of the signals on the register leads 538, 540, and 542 are downloaded to REGISTERS block 536 of the video encoder/decoder chip 112 from data bus 106 via register download bus 128. The output leads of control block 506 comprise CONV_ROW control leads 546, CONV_COL control leads 548, DWT control leads 550, 552, and 554, memory control leads 2106 and 2108, DWT address generator muxcontrol leads 544.

Counter block 2102 generates the signals row_count, row_carry, col_count, col_carry, octave, and channel, and provides these signals to combinatorial logic block 2104. Among other operations, counter 2102 generates the signals row_count and row_carry by counting the sequence of data values from 0 up to ximage, where ximage represents the horizontal dimension of the image received on leads 540. Similarly, counter 2102 generates the signals col_count and col_carry by counting the sequence of data values from 0 up to yimage, where yimage represents the vertical dimension of the image received on leads 542. The inputs to combinatorial logic block 2104 comprise the outputs of counter block 2102 as well as the inputs direction, ximage, yimage and sync to control block 508. The output control sequences of combinatorial logic block 2104 are combinatorially generated from the signals supplied to logic block 2104.

30

45

After the Y data values of an image have been transformed, the chrominance components U and V of the image are transformed. In the presently described specific embodiment of the present invention, a 4:1:1 format of Y:U:V values is used. Each of the U and V matrices of data values comprises half the number of rows and columns as does the Y matrix of data values. The wavelet transform of each of these components of chrominance is similar to the transformation of the Y data values except the line delays in the CONV_COL are shorter to accommodate the shorter row length and the size of the matrices corresponding to the matrix of Table 1 is smaller.

Not only does the discrete wavelet transform circuit of Figure 5 transform image data values into a multioctave sub-band decomposition using a forward discrete wavelet transformation, but the discrete wavelet transform circuit of Figure 5 can be used to perform a discrete inverse wavelet transform on transformed-image data to convert a sub-band decomposition back into the image domain. In one octave of an inverse discrete wavelet transform, the inverse column convolver 504 of Figure 5 operates on transformed-image data values read from memory unit 116 via leads 526, lines 528 and multiplexer mux2 512 and the inverse row convolver 502 operates on the data values output by the column convolver supplied via leads 524, lines 525 and multiplexer mux1 510.

Figures 22 and 23 show control signals and data flow for the column convolver 504 of Figure 5 when column convolver 504 performs an inverse octave 1 discrete wavelet transform on transformed-image data located in memory unit 116. As illustrated in Figure 23, the data value output from adder/subtractor block 1326 of Figure 13 at time t=4 is 32{(b-a)HHHH₀₀ + (c-d)HHHG₀₀}. The column convolver therefore processes the first two values HHHH₀₀ and HHHG₀₀ in accordance with the two coefficient start reconstruction filter (inverse transform filter) set forth in equation 52 of copending Patent Cooperation Treaty (PCT) application filed March 30, 1994, entitled "Data Compression and Decompression". Subsequently, blocks 1332 and 1326 output values indicating that the column convolver performs the four coefficient odd and even reconstruction filters (interleaved inverse transform filters) of equations 20 and 19 of copending Patent Cooperation Treaty (PCT) application filed March 30, 1994, entitled "Data Compression and Decompression". Fig. 23 illustrates that the column convolver performs the two coefficient end reconstruction filter (inverse transform filter) on the last two data values HHHH₁₀ and HHHG₁₀ (see time t=20) of the first column of transformed data values in accordance with equation 59 of copending Patent Cooperation Treaty (PCT) application filed March 30, 1994, entitled "Data Compression and Decompression". The data values output from the column convolver of Figure 13 are supplied to the row convolver 502 of Figure 5 via lines 525 and multiplexer mux1 510.

Figures 24 and 25 show control signals and data flow for the row convolver 502 of Figure 5 when the row convolver performs an inverse octave 1 discrete wavelet transform on the data values output from the column

convolver. The column convolver 504 has received transformed values HHHH₀₀ ... HHGH₀₁ and so forth as illustrated in Fig. 23 and generated the values HHH₀₀ ... HHG₀₁ and so forth, as illustrated in Fig. 22, onto output leads 524. Row convolver 502 receives the values HHH₀₀ ... HHG₀₁ and so forth as illustrated in Fig. 24 and generates the values HH₀₀, HH₀₁, HH₀₂ and so forth as illustrated in Fig. 24 onto output leads 520 of row convolver 502. The data flow of Fig. 25 indicates that the row convolver performs the start reconstruction filter on the first two data values of a row, performs the odd and even reconstruction filters on subsequent non-boundary data values, and performs the end reconstruction filter on the last two data values of a row. The HH data values output from row convolver 502 are written to memory unit 116 into the memory locations corresponding with the HH data values shown in Fig. 16.

To inverse transform the octave 0 data values in memory unit 116 into the image domain, the column convolver 504 and the row convolver 502 perform an inverse octave 0 discrete wavelet transform. Figures 28 and 27 show the control signals and the data flow for the column convolver 504 of Figure 5 when the column convolver performs an inverse octave 0 discrete wavelet transform on transformed image data values in memory unit 116. The data values output from the column convolver are then supplied to the row convolver 502 of Figure 5 via lines 528 and multiplexer mux1 510.

10

30

Figures 28 and 29 show control signals and data flow for the row convolver 502 of Figure 5 when the row convolver performs an inverse octave 0 discrete wavelet transform on the data output from the column convolver to inverse transform the transformed-image data back to the image domain. Column convolver 504 receives transformed values HH_{00} ... GH_{03} and so forth as illustrated in Fig. 27 and generates the values H_{00} ... G_{03} and so forth as illustrated in Fig. 28 onto output leads 524. Row convolver 502 receives the values H_{00} ... G_{03} and so forth, as illustrated in Fig. 28, and generates the inverse transformed data values D_{00} , D_{01} , D_{02} ... D_{07} and so forth, as illustrated in Fig. 28, onto output leads 520 of row convolver 502. The inverse transformed data values output from row convolver 502 are written to memory unit 114.

The control signals and the data flows of Figures 22, 23, 24, 25, 26, 27, 28 and 29 comprise the inverse transformation from octave 1 to octave 0 and from octave 0 back into image domain inverse transformed data values which are substantially the same as the original data values of the matrix Table 1. The control signals which control the row convolver and column convolver to perform the inverse transform are generated by control block 506. The addresses and control signals used to read data values from and write data values to memory units 116 and 114 are generated by the DWT address generator block 508 under the control of control block 506.

After the inverse wavelet transform of the Y matrix of transformed data values is completed, the U and V matrices of transformed data values are inverse transformed one after the other in a similar way to the way the Y matrix was inverse transformed.

Figure 30 is a block diagram of the DWT address generator block 508 of Figure 5. The DWT address generator block 508 supplies read and/or write addresses to the memory units 116 and 114 for each octave of the forward and inverse transform. The DWT address generator block 508 comprises a read address generator portion and a write address generator portion. The read address generator portion comprises multiplexer 3006, adder 3010, multiplexer 3002, and resettable delay element 3014. The write address generator portion likewise comprises multiplexer 3008, adder 3012, multiplexer 3004, and resettable delay element 3016. The DWT address generator is coupled to the control block 506 via control leads 534, 556, and 544, to memory unit 116 via address leads 3022, and to memory unit 114 via address leads 3020. The input leads of DWT address generator 508 comprise the DWT address generator read control leads 534, the DWT address generator write controi leads 544, and the muxcontrol lead 534. The DWT address generator read control leads 534, in turn, comprise 6 leads which carry the values col_end_R, channel_start_R, reset_R, oct_add_factor_R, incr_R, base_u_R, and base_v_R. The DWT address generator write control leads 544, in turn, comprise leads which carry the values col_end_W, channel_start_W, reset_W, oct_add_factor_W, incr_W, base_u_W, and base_v_W. All signals contained on these leads are provided by control block 506. The output leads of DWT address generator block 508 comprise address leads 3022 which provide address information to memory unit 116, and address leads 3020 which provide address information to memory unit 114. The addresses provided on leads 3022 can be either read or write addresses, depending on the cycle of the DWT transform circuit 122 as dictated by control signal muxcontrol provided by control block 506 on lead 556. The addresses provided on leads 3020 are write-only addresses, because memory unit 114 is only written to by the DWT transform

Memory locations of a two-dimensional matrix of data values such as the matrices of Table 1, Figure 12 and Figure 16 may have memory location addresses designated 0, 1, 2 and so forth, the addresses increasing by one left to right across each row and increasing by one to skip from the right most memory location at the end of a row to the left most memory location of the next lower row. To address successive data values in a matrix of octave 0 data values, the address is incremented by one to read each new data value D from the

matrix.

15

35

55

For octave 1, addresses are incremented by two because the HH values are two columns apart as illustrated in Figure 16. The row number, however, is incremented by two rather than one because the HH values are located on every other row. The DWT address generator 508 in octave 1 therefore increments by two until the end of a row is reached. The DWT address generator then increments once by ximage + 2 as can be seen from Figure 16. For example, the last HH value in row 0 of Figure 16 is HH₀₃ at memory address 6 assuming HH₀₀ has an address of 0 and that addresses increment by one from left to right, row by row, through the data values of the matrix. The next HH value is in row two, HH₁₀, at memory address 16. The increment factor in a row is therefore incr = 2^{octave} . The increment factor at the end of a row is oct_add_factor = $(2^{\text{octave}} - 1)$ • ximage + 2^{octave} for octave ≥ 0 , where ximage is the x dimension of the image.

In some embodiments, the transformed Y data values are stored in memory unit 116 from addresses 0 through (ximage • yimage - 1), where yimage is the y dimension of the matrix of the Y data values. The transformed U data values are then stored in memory unit 116 from address base_u up to base_v - 1, where:

Similarly, the transformed V data values are stored in memory unit 116 at addresses beginning at address base_v.

The operation of the read address generator portion in Figure 30 is representative of both the read and write portions. In operation, multiplexer base_mux 3002 of Figure 30 sets the read base addresses to be 0 for the Y channel, base_u_R for the U channel, and base_v_R for the V channel. Multiplexer 3002 is controlled by the control signals channel_start_R which signifies when each Y, U, V channel starts. Multiplexer mux 3008 sets the increment factor to be Incr_R, or, at the end of each row, to oct_add_factor_R. The opposite increment factor is supplied to adder 3010 which adds the increment factor to the current address present on the output leads of delay elements 3014 so as to generate the next read address, next_addr_R. The next read address next_addr_R is then stored in the delay element 3014.

In some embodiments in accordance with the present invention, tables of incr_R and oct_add_factor_R for each octave are downloaded to REGISTERS block 536 on the video encoder/decoder chip 112 at initialization via download registers bus 128. These tables are passed to the control block 506 at initialization. To clarify the illustration, the leads which connect REGISTERS block 536 to control block 506 are not included in Figure 5. In other embodiments, values of incr_R and oct_add_factor_R are precalculated in hardware from the value of ximage using a small number of gates located on-chip. Because the U and V matrices have half the number of columns as the Y matrix, the U and V jump tables are computed with ximage replaced by $\frac{ximage}{2}$, a one bit shift. Because the tree encoder/decoder restricts ximage to be a multiple of $2^{(OCT+1)} > 2^{OCDEMP}$.

the addition of 2000 in the oct_add_factor is, in fact, concatenation. Accordingly, only the factor (2000 vimage must be calculated and downloaded. The jump tables for the U and V addresses can be obtained from the Y addresses by shifting this factor one bit to the right and then concatenating with 2000 vite. Accordingly, appropriate data values of a matrix can be read from a memory storing the matrix and processed data values can be written back into the matrix in the memory to the appropriate memory locations.

Figures 31 and 32 are block diagrams of one embodiment of the tree processor/encoder-decoder circuit 124 of Figure 1. Figure 31 illustrates the circuit in encoder mode and Figure 32 illustrates the circuit in decoder mode. Tree processor/encoder-decoder circuit 124 comprises the following blocks: DECIDE block 3112, TP_ADDR_GEN block 3114, quantizer block 3116, MODE_CONTROL block 3118, Huffman encoder-decoder block 3120, buffer block 3122, CONTROL_COUNTER block 3124, delay element 3126, delay element 3128, and VALUE_REG-ISTERS block 3130.

The tree processor/encoder-decoder circuit 124 is coupled to FIFO buffer 120 via input/output data leads 130. The tree processor/encoder-decoder circuit 124 is coupled to memory unit 116 via an old frame data bus 3102, a new frame data bus 3104, an address bus 3108, and memory control buses 3108 and 3110. The VAL-UE_REGISTERS block 3130 of the tree processor/encoder-decoder circuit 124 is coupled to data bus 106 via a register download bus 128. Figures 31 and 32 illustrate the same physical hardware; the encoder and decoder configurations of the hardware are shown separately for clarity. Although two data buses 3104 and 3102 are illustrated separately in Figure 31 to facilitate understanding, the new and old frame data buses may actually share the same pins on video encoder/decoder chip 112 so that the new and old frame data are time multiplexed on the same leads 526 of memory unit 116 as illustrated in Figure 5. Control buses 3108 and 3110 of Figure 31 correspond with the control lines 2108 in Figure 5. The DWT address generator block 508 of the discrete wavelet transform circuit 122 and the tree processor address generator block 3114 of the tree processor/encoder-decoder circuit 124 access memory unit 116 therefore may use the same physical address, data and

control lines.

Figure 33 illustrates an embodiment of DECIDE block 3112. A function of DECIDE block 3112 is to receive a two-by-two block of data values from memory unit 116 for each of the old and new frames and from these two-by-two blocks of data values and from the signals on leads 3316, 3318, 3320 and 3322, to generate seven flags present on leads 3302, 3304, 3306, 3308, 3310, 3312 and 3314. The MODE_CONTROL block 3118 uses these flags as well as values from VALUE_REGISTERS block 3130 supplied via leads 3316, 3318 and 3320 to determine the mode in which the new two-by-two block will be encoded. The addresses in memory unit 116 at which the data values of the new and old two-by-two blocks are located and determined by the address generator TP_ADDR_GEN block 3114.

The input signal on register lead 3316 is the limit value output from VALUE_REGISTERS block 3130. The input signal on register leads 3318 is the gatep value output from VALUE_REGISTERS block 3130. The input signal on register lead 3320 is the compare value output from VALUE_REGISTERS block 3130. The input signal on register lead 3322 is the octave value generated by TP_ADDR_GEN block 3114 as a function of the current location in the tree of the sub-band decomposition. As described in copending Patent Cooperation Treaty (PCT) application filed March 30, 1994, entitled "Data Compression and Decompression" at equations 62-71, the values of the flags new_z, nz_flag, origin, noflag, no_z, oz_flag, and motion, produced on leads 3302, 3304, 3306, 3308, 3310, 3312, and 3314, respectively, are determined in accordance with the following equations:

$$nz = \sum_{0 \le x, y \le 1} |new(x)(y)|$$
 (equ. 1)

$$oz = \sum_{0 \le x, y \le 1} |old(x)(y)|$$
 (equ. 2)

$$no = \sum_{0 \le x, y \le 1} |new(x)[y] - old(x)[y]$$
 (equ. 3)

$$nz_flag = nz < limit$$
 (equ. 4)
 $noflag = no < compare$ (equ. 5)
 $origin = nz \le no$ (equ. 6)
 $motion = ((nz + oz) << octave) \le no$ (equ. 7)
 $new_z = |new_z| [y] |< qstep,$
 $for 0 \le x, y \le 1$ (equ. 8)
 $no_z = |new_z| [y] - old_z| [y] |< qstep,$
 $for 0 \le x, y \le 1$ (equ. 9)
 $oz_flag = old_z| [y] = 0,$
 $for all 0 \le x, y, \le 1$ (equ. 10)

The DECIDE block 3112 comprises subtractor block 3324, absolute value (ABS) blocks 3326, 3328, and 3330, summation blocks 3332, 3334, and 3336, comparator blocks 3338, 3340, 3342, 3344, 3346, 3350, and 3352, adder block 3354, and shift register block 3356. The value output by ABS block 3326 is the absolute value of the data value new[x][y] on leads 3104. Similarly, the value output by ABS block 3328 is the absolute value of the data value old[x][y] on leads 3102. The value output by ABS block 3330 is the absolute value of the difference between the data values new[x][y] and old[x][y]. Comparator 3338, coupled to the output leads of ABS block 3326, unasserts new_z flag on lead output 3302 if qstep is less than the value output by block 3326. Block 3332 sums the last four values output from block 3326 and the value output by block 3332 is supplied to comparator block 3340. Comparator block 3340 compares this value to the value of limit 3316. The flag nz_flag 3304 is asserted on lead 3304 if limit is greater than or equal to the value output by block 3332. This value corresponds to nz_flag in equation 4. Summation block 3334 similarly sums the four most recent values output by block 3354 being supplied to shift register block 3356. The shift register block 3356 shifts the value received to the left by octave bits. Summation block 3336 adds the four most recent values output by block 3342 compares the value output by block 3320 to the value output by block

3336 and asserts the motion flag in accordance with equation 7. The origin flag on output lead 3306 is asserted when the value output by block 3332 is less than the value output by 3338. This value corresponds to origin in equation 6 above. The value output by block 3336 is compared to the value compare by block 3344 such that flag noflag is asserted when compare is greater than the value output from block 3336. Block 3346 compares the value output by block 3330 to the value qstep such that flag no_z is unasserted when qstep is less. This corresponds to flag no_z in equation 9. The old input value on leads 3102 is compared to the value 0 by block 3350 such that flag oz_flag on lead 3312 is asserted when each of the values of the old block is equal to 0. This corresponds to oz_flag in equation 10 above. The seven flags produced by the DECIDE block of Figure 33 are passed to the MODE_CONTROL block 3118 to determine the next mode.

The tree processor/encoder-decoder circuit 124 of Figure 31 comprises delay elements 3126 and 3128. Delay element 3126 is coupled to the NEW portion of memory unit 116 via new frame data bus 3104 to receive the value new[x][y]. Delay element 3128 is coupled to the OLD portion of memory unit 118 via old frame data bus 3102 to receive the value old[x][y]. These delay elements, which in some embodiments of the invention are implemented in static random access memory (SRAM), serve to delay their respective input values read from memory unit 116 for four cycles before the values are supplied to quantizer block 3116. This delay is needed because the DECIDE block 3112 introduces a four-cycle delay in the dataflow as a result needing to read the four most recent data values before the new mode in which those data values will be encoded is determined. The delay elements therefore synchronize signals supplied to quantizer block 3116 by the MODE_CONTROL block 3118 with the values read from memory unit 116 which are supplied to quantizer block 3116.

10

20

40

The tree processor/encoder-decoder circuit 124 of Figures 31 and 32 comprises a VALUE_REGISTERS block 3130. The VALUE_REGISTERS block 3130 serves the function of receiving values from an external source and asserting these values onto leads 3316, 3318, 3320, 3132, 3134 and 3136, which are coupled to other blocks in the tree processor/encoder-decoder 124. In the presently described embodiment the external source is data bus 106 and VALUE_REGISTERS block 3130 is coupled to data bus 108 via a download register bus 128. Register leads 3316 carry a signal corresponding to the value of limit and are coupled to DECIDE block 3112 and to MODE_CONTROL block 3118. Register leads 3318 carry signals indicating the value of gstep and are coupled to DECIDE block 3112 and to MODE_CONTROL block 3118. Register leads 3320 carry signals indicating the value of compare and are coupled to DECIDE block 3112 and to MODE_CONTROL block 3118. Register leads 3132 carry signals indicating the value of ximage and are coupled to TP_ADDR_GEN block 3114 and to MODE_CONTROL block 3118. Register leads 3134 carry signals indicating the value of yimage and are coupled to TP_ADDR_GEN block 3114 and to MODE_CONTROL block 3118. Register lead 3136 carries a signal corresponding to the value of direction and is coupled to TP_ADDR_GEN block 3114, MODE_CONTROL block 3118, buffer block 3122, Huffman encoder-decoder block 3120, and quantizer block 3116. To clarify the illustration, only selected ones of the connections between the VALUE_REGISTERS block 3130 and other blocks of the tree processor/encoder-decoder circuit 124 are illustrated in Figures 31 and 32. VALUE_REGISTERS block 3130 is, in some embodiments, a memory mapped register addressable from bus

Figure 34 is a block diagram of an embodiment of address generator TP_ADDR_GEN block 3114 of Figure 32. The TP_ADDR_GEN block 3114 of Figure 34 generates addresses to access selected two-by-two blocks of data values in a tree of a sub-band decomposition using a counter circuit (see Figures 27-29 of copending Patent Cooperation Treaty (PCT) application filed March 30, 1994, entitled *Data Compression and Decompression" and the corresponding text). Figure 34 illustrates a three-octave counter circuit. The signals supplied to TP_ADDR_GEN block 3114 are provided by MODE_CONTROL block 3118, CONTROL_COUNTER block 3124, and VALUE_REGISTERS block 3130. MODE_CONTROL block 3118 is coupled to TP_ADDR_GEN block 3114 by leads 3402 which carry the three bit value new_mode. CONTROL_COUNTER 3124 is coupled to TP_ADDR_GEN block 3114 by leads 3404 and 3406 which carry signals read_enable and write_enable, respectively. VALUE_REGISTER block 3130 is coupled to TP_ADDR_GEN block 3114 by register leads 3132 which carry a signal indicating the value of ximage. The output leads of TP_ADDR_GEN block 3114 comprise tree processor address bus 3108 and octave leads 3322. The address generator TP_ADDR_GEN block 3114 comprises a series of separate counters: counter TreeRoot_x 3410, counter TreeRoot_y 3408, counter C3 3412, counter C2 3414, counter C1 3416, and counter sub_count 3418. TP_ADDR_GEN block 3114 also comprises CONTROL_ENABLE block 3420, multiplexer 3428, multiplexer 3430, NOR gate 3436, AND gates 3422, 3424 and 3426, AND gates 3428, 3430 and 3432, multiplier block 3432 and adder block 3434.

Counter TreeRoot_x 3410 counts from 0 up to $\frac{ximage}{20c7+1}$ - 1 and counter TreeRoot_y 3408 counts from 0

up to $\frac{yimage}{20cT+1}$ - 1, where OCT is the maximum number of octaves in the decomposition. Counters C3, C2, C1, and sub_count are each 2-bit counters which count from 0 up to 3, and then return to 0. Each of these counters

takes on its next value in response to a respective count enable control signal supplied by CONTROL_ENABLE block 3420. Figure 34 shows count enable control signals x_en, y_en, c3_en, c2_en, c1_en, and sub_en, being supplied to the counters TreeRoot_x, TreeRoot_y, C3, C2, C1 and sub_count, respectively. When one of the counters reaches its maximum value, the counter asserts a carry out signal back to the CONTROL_ENABLE block 3420. These carry out signals are denoted in Figure 34 as x_carry, y_carry, c3_carry, c2_carry, c1_carry, and sub_carry.

CONTROL_ENABLE block 3420 responds to input signal new_mode on leads 3402 and to the carry out signals to generate the counter enable signals. The octave signal output by CONTROL_ENABLE is the value of the octave of the transform of the data values currently being addressed. The c1_carry, c2_carry, and c3_carry signals are logically ANDed with the write_enable signal supplied from CONTROL_COUNTER block 450 before entering the CONTROL_ENABLE block 3420. This AND operation is performed by AND gates 3422, 3424, and 3426 as shown in Figure 34. The counter enable signals from CONTROL_ENABLE block 3420 are logically ANDed with the signal resulting from the logical ORing of read_enable and write_enable by OR gate 3436. These ANDing operations are performed by AND gates 3428, 3430, and 3432 as shown in Figure 34. AND gates 3422, 3424, 3426, 3428, 3430, and 3432 function to gate the enable and carry signals with the read_enable and write_enable signals such that the address space is cycled through twice per state, once for reading and once for writing.

The CONTROL_ENABLE block 3420 outputs the enable signals enabling selected counters to increment when the count value reaches 3 in the case of the 2-bit counters 3412, 3414, and 3418, or when the count value reaches $\frac{ximage}{20CT+1}$ - 1 in the case of TreeRoot_x 3410, or when the count value reaches $\frac{yimage}{20CT+1}$ - 1 in the case of TreeRoot_y 3408. The resulting x and y addresses of a two-by-two block of data values of a given octave in a matrix of data values are obtained from the signals output by the various counters as follows: For octave = 0:

20

25

30

35

50

Figure 34 and equations 11-16 illustrate how the x and y address component values are generated by multiplexers 3428 and 3430, respectively, depending on the value of octave. The (2) in equations 11-16 denotes the least significant bit of a 2-bit counter whereas the (1) denotes the most significant bit of a 2-bit counter. TreeRoot_x and TreeRoot_y are the multibit values output by counters 3410 and 3408, respectively. The output of multiplexer 3430 is supplied to multiplier 3432 so that the value output by multiplexer 3430 is multiplied by the value ximage. The value output by multiplier 3432 is added to the value output by multiplexer 3428 by adder block 3434 resulting in the actual address being output onto address bus 3106 and to memory unit 116.

Appendix A discloses one possible embodiment of CONTROL_ENABLE block 3420 of a three octave address generator described in the hardware description language VHDL. An overview of the specific implementation given in this VHDL code is provided below. The CONTROL_ENABLE block 3420 illustrated in Figure 34 and disclosed in Appendix A is a state machine which allows trees of a sub-band decomposition to be ascended or descended as required by the encoding or decoding method. The CONTROL_ENABLE block 3420 generates enable signals such that the counters generate four addresses of a two-by-two block of data values at a location in a tree designated by MODE_CONTROL block 3118. Instructions from the MODE_CONTROL block 3118 are read via leads 3402 which carry the value new_mode. Each state is visited for four consecutive cycles so that the four addresses of the block are output by enabling the appropriate counter C3 3412, C2 3414 or C1 3416. Once the appropriate counter reaches a count of 3, a carry out signal is sent back to CONTROL_ENABLE block 3420 so that the next state is entered on the next cycle.

Figure 35 is a state table for the TP_ADDR_GEN block 3114 of Figure 34 when the TP_ADDR_GEN block 3114 traverses all the blocks of the tree illustrated in Figure 36. Figure 35 has rows, each of which represents the generation of four address values of a block of data values. The (0-3) designation in Figure 35 represents the four values output by a counter. The names of the states (i.e., up0, up1, down1) do not indicate movement up or down the blocks of a tree but rather correspond with state names present in the VHDL code of Appendix A. (In Appendix A, the states down1, down2 and down3 are all referred to as down! to optimize the implementation.) The state up0 in the top row of Figure 35, for example, corresponds to addressing the values of two-by-two block located at the root of the tree of Figure 36. In the tree of Figure 36 there are three octaves. After

these four addresses of the two-by-two block at the root of the tree are generated, the tree may be ascended to octave 1 by entering the state upf.

Figure 36 illustrates a complete traversal of all the data values of one tree of a 3-octave sub-band decomposition as well as the corresponding states of the CONTROL_ENABLE block of Figure 35. One such tree exists for each of the "GH", "HG" and "GG" sub-bands of a sub-band decomposition.

First, before a tree of the sub-band decomposition is traversed, all low pass HHHHHH component values of the decomposition are addressed by setting counter sub_count to output 00. Counter C3 3412 is incremented through its four values. Counter TreeRoot_x is then incremented and counter C3 3412 is incremented through its four values again. This process is repeated until TreeRoot_x reaches its maximum value. The process is then repeated with TreeRoot_y being incremented. In this manner, all HHHHHHH low pass components are accessed. Equations 15 and 16 are used to compute the addresses of the HHHHHHH low pass component data values.

Next, the blocks of the "GH" subband of a tree given by TreeRoot_x and TreeRoot_y are addressed. This "GH" subband corresponds to the value sub_count = 10 (sub_count (1) = 1 and sub_count (2) = 0). The up0 state shown in Figure 35 is used the generate the four addresses of the root block of the "GH" tree in accordance with equation 15. The upi state shown in Figure 35 is then used such that addresses corresponding to equations 13 and 14 are computed to access the desired two-by-two block of data values in octave 1. The four two-bytwo blocks in octave 0 are then accessed in accordance with equations 11 and 12. With TreeRoot_x and Tree-Root_y and sub_count untouched, the states zz0, zz1, zz2 and zz3 are successively entered, four addresses being generated in each state. After each one of these four states is exited, the C2 counter 3414 is incremented by CONTROL_ENABLE block 3420 via the c2_en signal once in order to move to the next octave 0 block in that branch of the tree. After incrementing in state zz3 is completed, the left hand branch of the tree is exhausted. To move to the next two-by-two block, the C3 counter 3412 is incremented and the C2 counter 3414 is cycled through its four values to generate the four addresses of the next octave 1 block in state downl in accordance with equations 13 and 14. In this way, the TP_ADDR_GEN block 3114 generates the appropriate addresses to traverse the tree in accordance with instructions received from MODE_CONTROL block 3118. When the traversal of the "GH" sub-band tree is completed, the traversal of the sub-band decomposition moves to the corresponding tree of the next sub-band without changing the value of TreeRoot_x and TreeRoot_y. Accordingly, a "GH" "HG" and "GG" family of trees are traversed. After all the blocks of the three sub-band trees have been traversed, the TreeRoot_x and TreeRoot_y values are changed to move to another family of subband trees.

To move to the next family of sub-band trees, the counter TreeRoot_x 3410 is incremented, and the C3 3412, C2 3414, C1 3416 counters are returned to 0. The process of traversing the new "GH" tree under the control of the MODE_CONTROL block 3118 proceeds as before. Similarly, the corresponding "HG" and "GG" trees are traversed. After TreeRoot_x 3410 reaches its final value, a whole row of tree families has been searched. The counter TreeRoot_y 3408 is therefore incremented to move to the next row of tree families. This process may be continued until all of the trees in the decomposition have been processed.

The low pass component HHHHHH (when sub_count = 00) does not have a tree decomposition. In accordance with the present embodiment of the present invention, all of the low pass component data values are read first as described above and are encoded before the tree encoder reads and encodes the three subbands. The address of the data values in the HHHHHHH subband are obtained from the octave 3 x and y addresses with sub_count = 00. Counters C3 3412, TreeRoot_x 3410, and TreeRoot_y 3408 run through their respective values. After the low pass component data values and all of the trees of all the sub-bands for the Y data values have been encoded, the tree traversal method repeats on the U and V data values.

Although all the blocks of the tree of Figure 36 are traversed in the above example of a tree traversal, the MODE_CONTROL block 3118 may under certain conditions decide to cease processing data values of a particular branch and to move to the next branch of the tree as set forth in copending Patent Cooperation Treaty (PCT) application filed March 30, 1994, entitled "Data Compression and Decompression". This occurs, for example, when the value new_mode output by the MODE_CONTROL block 3118 indicates the mode STOP. In this case, the state machine of CONTROL_ENABLE block 3420 will move to, depending on the current location in the tree, either the next branch, or, if the branch just completed is the last branch of the last tree, the next

Figure 34 illustrates control signal inputs read_enable and write_enable being supplied to TP_ADDR_GEN block 3114. These enable signals are provided because the reading of the new/old blocks and the writing of the updated values to the old frame memory occur at different times. To avoid needing two address generators, the enable signals of the counters C3 3412, C2 3414, and C1 3416 are logically ANDed with the logical OR of the read_enable and write_enable signals. Similarly, the carryout signals of these counters are logically ANDed with the write_enable signal. During time periods when the new/old blocks are read from memory, the

read_enable signal is set high and the write_enable signal is set low. This has the effect of generating the addresses of a two-by-two block, but disabling the change of state at the end of the block count. The counters therefore return to their original values they had the start of the block count so that the same sequence of four address values will be generated when the write_enable signal is set high. This time, however, the carry out is enabled into the CONTROL_ENABLE block 3420. The next state is therefore entered at the conclusion of the block count. In this manner, the address space is cycled through twice per state, once for reading and once for writing.

Figure 37 is a block diagram of one embodiment of quantizer block 3116 of Figure 31. As shown in Figure 31, quantizer block 3116 is coupled to MODE_CONTROL block 3118, a Huffman encoder-decoder block 3120, delay block 3126, delay block 3128, and VALUE_REGISTERS block 3130. Input lead 3702 carries the signal difference from MODE_CONTROL block 3118 which determines whether a difference between the new frame and old frame is to be quantized or whether the new frame alone is to be quantized. Values new[x][y] and old[x][y] are supplied on lines 3704 and 3706, respectively, and represent values from memory unit 116 delayed by four clock cycles. Input leads 3708 and 3710 carry the values sign_inv and qindex_inv from the Huffman encoder-decoder block 3120, respectively. Register leads 3318 and 3136 carry signals corresponding to the values gstep and direction from VALUE_REGISTERS block 3130, respectively.

During encoding, quantizer block 3116 performs quantization on the values new[x][y], as dictated by the signal difference and using the values old[x][y], and generates the output values qindex onto output leads 3712, sign onto output lead 3714, and a quantized and then inverse quantized value old[x][y] onto data bus 3102. The quantized and inverse quantized value old[x][y] is written back into memory unit 116.

During decoding, quantizer block 3116 performs inverse quantization on the values old[x][y], as dictated by the signals difference, sign_inv, and qindex_inv, and generates an inverse quantized value, old[x][y], which is supplied to the old portion of memory unit 116 via bus 3102. Lead 3136 carries the value direction supplied by the VALUE_REGISTERS 3130.

25

The value direction controls whether the quantizer operates in the encoder mode or the decoder mode. Figure 37 illustrates that multiplexers 3716 and 3718 use the direction signal to pass signals corresponding to the appropriate mode (sign and qindex for encoder mode; sign_inv and qindex_inv for decoder mode). Multiplexer 3720 passes either the difference of the new and old data values or passes the new value depending on the value of the difference signal. Absolute value block ABS 3722 converts the value output by multiplexer 3720 to absolute value form and supplies the absolute value form value to block 3724. The output leads of multiplexer 3720 are also coupled to sign block 3726. Sign block 3726 generates a sign signal onto lead 3714 and to multiplexer 3716.

Block 3724 of the quantizer block 3116 is an human visual system (HVS) weighted quantizer having a threshold of qstep. The value on input leads 3728 denoted mag in Figure 37 is quantized via a modulo-qstep division (see Figures 30 and 31 of copending Patent Cooperation Treaty (PCT) application filed March 30, 1994, entitled "Data Compression and Decompression" and the corresponding text). The resulting quantized index value qindex is output onto leads 3712 to the Huffman encoder block 3120. Multiplexer 3716 receives the sign signal on leads 3714 from block 3726 and also the sign_inv signal on lead 3708. Multiplexer 3716 passes the sign value in the encoder mode and passes the sign_inv value in the decoder mode. Likewise, multiplexer 3718 has as two inputs, the qindex signal on leads 3712 and the qindex_inv signal on leads 3710. Multiplexer 3718 passes the qindex value in the encoder mode and the qindex_inv value in the decoder mode. Inverse quantizer block 3730 inverse quantizes the value output by multiplexer 3718 by the value qstep to generate the value qvalue. Block NEG 3732 reverses the sign of the value on the output lead of block 3730, denoted qvalue in Figure 37. Multiplexer 3734 chooses between the positive and negative versions of qvalue as determined by the signal output from multiplexer 3716.

In the encoder mode, if the difference signal is asserted, then output leads 3712 qindex carry the quantized magnitude of the difference between the new and old data values and the output leads 3736 of multiplexer 3734 carry the inverse quantization of this quantized magnitude of the difference between the new and old values. In the encoder mode, if the difference input is deasserted, then the output leads 3712 qindex carry only the quantized magnitude of the new data value and the value on leads 3736 is the inverse quantization of the quantized magnitude of the new data value.

Adder block 3738 adds the inverse quantized value on leads 3736 to the old[xi[y] data value and supplies the result to multiplexer 3740. Accordingly, when the difference signal is asserted, the difference between the old inverse quantized value on leads 3706 and the inverse quantized value produced by inverse quantizer 3730 is determined by adding in block 3738 the opposite of the inverse quantized output of block 3730 to the old inverse quantized value. Multiplexer 3740 passes the output of adder block 3738 back into the OLD portion of memory unit 116 via bus 3102. If, on the other hand, the difference signal is not asserted, then multiplexer 3740 passes the value on leads 3736 to the OLD portion of memory unit 116 via bus 3102. Accordingly, a frame

of inverse quantized values of the most recently encoded frame is maintained in the old portion of memory unit 116 during encoding.

In accordance with one embodiment of the present invention, the value of qstep is chosen so that qstep = 2^n , where $0 \le n \le 7$, so that quantizer block 3724 and inverse quantizer 3730 perform only shifts by n bits. Block 3724 then becomes in VHDL, where >> denotes a shift to the left, and where mag denotes the value output by block 3722:

```
CASE n is

WHEN 0 => qindex: = mag;

WHEN 1 => qindex: = mag >> 1;

WHEN 7 => qindex: = mag >> 7;

END CASE;

Similarly, block 3730 is described in VHDL as follows:

CASE n is

WHEN 0 => qvalue : = qindex;

WHEN 1 => qvalue : = (qindex << 1) & "0";

WHEN 2 => qvalue : = (qindex << 2) & "01";
```

10

15

20

30

35

WHEN 7 => qvalue : = (qindex << 7) & "0111111";

where << denotes a shift to the right and where & denotes concatenation. The factor concatenated after the shift is $2^{n-1}-1$.

The tree processor/encoder-decoder circuit 124 of Figure 31 also includes a MODE_CONTROL block 3118. In the encoder mode, MODE_CONTROL block 3118 determines mode changes as set forth in copending Patent Cooperation Treaty (PCT) application filed March 30, 1994, entitled "Data Compression and Decompression" when trees of data values are traversed to compress the data values into a compressed data stream. In the decoder mode, MODE_CONTROL block 3118 determines mode changes as set forth in copending Patent Cooperation Treaty (PCT) application filed March 30, 1994, entitled "Data Compression and Decompression" when trees of data values are recreated from an incoming compressed data stream of tokens and data values.

MODE_CONTROL block 3118 receives signals from DECIDE block 3112, CONTROL_COUNTER block 3124, TP_ADDR_GEN block 3114, and VALUE_REGISTERS block 3130. MODE_CONTROL block 3118 receives the seven flag values from DECIDE block 3112. The input from CONTROL_COUNTER block 3124 is a four-bit state vector 3138 indicating the state of the CONTROL_COUNTER block 3124. Four bits are needed because the CONTROL_COUNTER block 3124 can be in one of nine states. The input from TP_ADDR_GEN block 3114 is the octave signal carried by leads 3322. The VALUE_REGISTERS block 3130 supplies the values on leads 3316, 3318, 3320, 3132, 3134, and 3136 to MODE_CONTROL block 3118. Additionally, in the decoder mode, buffer 3122 supplies token values which are not Huffman decoded onto leads 3202 and to the MODE_CONTROL block 3118 as shown in Figure 32.

MODE_CONTROL block 3118 outputs a value new_mode which is supplied to TP_ADDR_GEN block 3114 via leads 3402 as well as a token length value T_L which is supplied to buffer block 3122 via leads 3140. In the encoder mode, MODE_CONTROL block 3118 also generates and supplies tokens to buffer block 3122 via leads 3202. Leads 3202 are therefore bidirectional to carry token values from MODE_CONTROL block 3118 to buffer block 3122 in the forward mode, and to carry token values from buffer 3122 to MODE_CONTROL block 3118 in the decoder mode. The token length value T_L, on the other hand, is supplied by MODE_CONTROL block 3118 to buffer block 3122 in both the encoder and decoder modes. MODE_CONTROL block 3118 also generates the difference signal and supplies the difference signal to quantizer block 3116 via lead 3142. MODE_CONTROL block 3118 asserts the difference signal when differences between new and old values are to be quantized and deasserts the difference signal when only new values are to be quantized. Appendix B is a VHDL description of an embodiment of the MODE_CONTROL block 3118 in the VHDL language.

In the encoding process, the MODE_CONTROL block 3118 initially assumes a mode, called pro_mode, from the block immediately below the block presently being encoded in the present tree. For example, the blocks in Figure 36 corresponding to states zz0, ..., zz3 in the left-most branch inherit their respective pro_modes from the left-most octave 1 block. Similarly, the left-most octave 1 block in Figure 36 inherits its pro_mode from the root of the tree in octave 2. After the data values of the new and old blocks are read and after the DECIDE block 3112 has generated the flags for the new block as described above, the state machine of

MODE_CONTROL block 3118 determines the new_mode for the new block based on the new data values, the flags, and the pro-mode. The value of new_mode, once determined, is then stored as the current mode of the present block in a mode latch. There is one mode latch for each octave of a tree and one for the low pass data values. The mode latches form a stack pointed to by octave so that the mode latches contain the mode in which each of the blocks of the tree was encoded.

The tree processor circuit of Figures 31 and 32 also comprises a Huffman encoder-decoder block 3120. In the encoder mode, inputs to the Huffman encoder-decoder block 3120 are supplied by quantizer block 3116. These inputs comprise the qindex value and the sign signal and are carried by leads 3712 and 3714, respectively. The outputs of Huffman encoder-decoder 3120 comprise the Huffman encoded value on leads 3142 and the Huffman length H_L on leads 3144, both of which are supplied to buffer block 3122.

10

15

50

In the decoder mode, the input to the Huffman encoder-decoder block 3120 is the Huffman encoded value carried by leads 3204 from buffer block 3122. The outputs of the Huffman encoder-decoder 3120 comprise the Huffman length H_L on leads 3144 and the sign_inv and qindex_inv values supplied to quantizer block 3116 via leads 3708 and 3710, respectively.

The Huffman encoder-decoder block 3120 implements the Huffman table shown in Table 2 using combinatorial logic.

qindex	Huffman code
-38512	1100000011111111
-2237	1 1 0 0 0 0 0 0 1 1 1 1 (qindex -22)
-721	1 1 0 0 0 0 0 0 (qindex -7)
-6	1100001
•	
•	•
-2	1 1 0 1
-1	1 1 1
0	0
1	101
2	1001
•	T .
•	
6	10000001
7 21	1000000 (qindex -7)
22 37	100000001111 (qindex -22)
38 511	100000001111111

Table 2

In the encoder mode, qindex values are converted into corresponding Huffman codes for incorporation into the compressed data stream. Tokens generated by the MODE_CONTROL block 3118, on the other hand, are not encoded but rather are written directly into the compressed data stream.

Figure 38 illustrates one possible embodiment of buffer block 3122 of Figures 31 and 32. The function of buffer block 3122 in the encoder mode is to assemble encoded data values and tokens into a single serial compressed data stream. In the decoder mode, the function of buffer block 3122 is to deassemble a compressed

serial data stream into encoded data values and tokens. Complexity is introduced into buffer block 3122 due to the different lengths of different Huffman encoded data values. As illustrated in Figure 31, buffer 3122 is coupled to FIFO buffer 120 via input-output leads 130, to MODE_CONTROL block 3118 via token value leads 3202 and token length leads 3140, to Huffman encoder-decoder 3120 via leads 3144 and Huffman length leads 3144, to CONTROL_COUNTER 3124 via cycle select leads 3802, and to VALUE_REGISTERS 3130 via leads 3136.

The direction signal carried on leads 3136 from VALUE_REGISTERS block 3130 determines whether the buffer block 3122 operates in the encoder mode or in the decoder mode. In encoder mode, multiplexers 3804, 3806, 3808 and 3814 select the values corresponding to their "E" inputs in Figure 38. In the encoder mode, the buffer block 3122 processes the Huffman encoded value signal present on leads 3142, the token value signal present on leads 3202, the cycle select signal on leads 3802, the Huffman length signal H_L on leads 3144, and the token length signal T_L on leads 3140. The cycle select signal, supplied by CONTROL_COUNTER block 3124 via leads 3802, is supplied to multiplexers 3810 and 3812 to control whether a Huffman encoded value (received from Huffman encoder-decoder block 3120) or whether a non-encoded token value (received from MODE_CONTROL block 3118) is the value presently being assembled into the output data stream.

Figure 39 illustrates a simplified diagram of the buffer block 3122 of Figure 38 when configured in encoder mode. The value s_t is a running modulo sixteen sum of the input token length values and Huffman value length values. The circuit which determines s_t comprises adder block 3902, modulo sixteen divider block 3904, and delay block 3906. When the incoming length value added to the prior value s_t produces a length result of sixteen or greater, block 3904 subtracts sixteen from this length result to determine the new value of s_t. Comparator block 3908 also sends a signal high_low to input lead 3916 of multiplexer 3901 indicating that s_t has exceeded sixteen. Figure 39 shows a barrel shifter 3912 receiving data input values from the output data leads of multiplexer 3901 and from the output data leads of multiplexer 3810. Barrel shifter 3912 sends a 32-bit output signal to a 32-bit buffer 3914. The lower 16-bit output of 32-bit buffer 3914 constitutes the encoded bit stream output of the video encoder/decoder chip which is output onto input/output leads 130.

When the prior value of s, plus the incoming value length is sixteen or greater, then the lower sixteen bits of buffer 3914 are sent out to FIFO buffer 120 and multiplexer 3901 is set to pass the upper sixteen bits of buffer 3914 back into the lower sixteen bit positions in barrel shifter 3912. The value s, is then decremented by sixteen. These passed back bits will next become some of the bits in the lower sixteen bits of buffer 3914, on which a subsequent incoming encoded value or token received from multiplier 3810 will be stacked by the barrel shifter starting at location S, to make sixteen or more packed bits.

Alternatively, if the value of s₁ plus the length of the new incoming value is less than sixteen, then multiplexer 3901 is controlled to pass the lower sixteen bits of buffer 3914 back to barrel shifter 3912 and no bits are applied to FIFO buffer 120. The bits of a subsequent incoming encoded value or taken from multiplexer 3810 will be stacked on top of the bits of prior encoded data values or tokens in barrel shifter 3912. Because the value S₇ did not exceed sixteen, s₇ is not decremented by sixteen.

35

50

Figure 40 illustrates a typical output of the barrel shifter 3912 of the buffer 3122 in encoder mode. The maximum length of a Huffman encoded word is sixteen bits. All tokens are two bits in length, where length is the number of bits in the new encoded value or token. The value s in Figure 40 indicates the bit position in the barrel shifter 3912 immediately following the last encoded data value or token present in the barrel shifter. Accordingly, a new encoded value or token is written into barrel shifter 3912 at positions s... s + length. The resulting 32-bit output of the barrel shifter is rewritten to the 32-bit buffer 3914. The comparator block compares the new value of s + length to sixteen. If this value s + length is sixteen or greater as illustrated in Figure 40, then the control signal high_low on multiplexer input lead 3916 is asserted. The lower sixteen bits of the buffer are therefore already completely packed with either bits of data values and/or with bits of tokens. These lower sixteen bits are therefore output to comprise part of the output data stream. The upper sixteen bits, which are incompletely packed with data values and/or tokens, are sent back to the lower sixteen bit positions in the barrel shifter so that the remaining unpacked bits in the lower sixteen bits can be packed with new data bits or new token bits.

If, on the other hand, this value s + length is fifteen or less, then there remain unpacked bits in the lower sixteen bit positions in barrel shifter 3912. These lower bits in barrel shifter 3912 can therefore not yet be output via buffer 3914 onto lines 130. Only when s + length is sixteen or greater will the contents of barrel shifter 3912 be written to buffer 3914 so that the lower sixteen bits will be output via leads 130.

In the decoder mode, buffer 3122 receives an encoded data stream on leads 130, the token length signal T_L on leads 3140 from MODE_CONTROL block 3118, the Huffman encoded length signal H_L on leads 3144, and the control signal cycle select on lead 3802. Multiplexers 3804, 3806, and 3808 are controlled to select values on their respective "D" inputs. Cycle select signal 3802 selects between the Huffman encoded length H_L and the token length T_L depending on whether a data value or a token is being extracted from the in-

coming data stream.

10

35

50

55

Figure 41 illustrates a simplified diagram of the buffer block 3122 configured in the decoder mode. The value s_i is a running modulo thirty-two sum of the input token length values and Huffman value length values. The circuit which determines the value of s_i comprises adder block 4002, modulo thirty-two divider block 4004, and delay block 4006. When the incoming length value added to s_i results in a value greater than thirty-two, modulo thirty-two divider block 4004 subtracts thirty-two from this value. A comparator block 4008 sends a signal to buffer 3914 Indicating when s_i has reached a value greater than or equal to thirty-two. Additionally, comparator block 4008 sends a signal to both buffer 3914 and to multiplexers 3901 and 4010 indicating when s_i has reached a value greater than or equal to sixteen.

Buffer 3122 in the decoder mode also comprises buffer 3914, multiplexers 3901 and 4010, and barrel shifter 4012. In the case of a Huffman encoded data value being the next value in the incoming data stream, sixteen bits of the encoded data stream that are present in barrel shifter 4012 are passed via output leads 3204 to the Huffman decoder block 3120. The number of bits in the sixteen bits that represent an encoded data value depends on the data value itself in accordance with the Huffman code used. In the case of a token being the next value in the incoming data stream, only the two most significant bits from barrel shifter 4012 are used as the token value which is output onto leads 3202 to MODE_CONTROL block 3118. The remaining fourteen bits are not output during this cycle. After a number of bits of either an encoded data value or a two-bit token is output, the value of si is updated to point directly to the first bit of the bits in barrel shifter 4012 which follows the bit last output. The circuit comprising adder block 4002, module block 4004, and delay element 4006 adds the length of the previously output value or token to s, modulo thirty-two to determine the starting location of the next value or token in barrel shifter 4012. Comparator block 4008 evaluates the value of si plus the incoming length value, and transmits an active value on lead 4014 when this value is greater than or equal to sixteen and also transmits an active value on lead 4016 if this value is greater than or equal to thirty-two. When si is greater or equal to sixteen, the buffer 3914 will read in a new sixteen bits of encoded bit stream bits into its lower half. When $s_i \ge 32$, the buffer 3914 will read a new sixteen bits into its upper half. The two multiplexers 4010 and 3910 following the buffer 3914 rearrange the order of the low and high halves of the buffer 3914 to maintain at the input leads of barrel shifter 4012 the original order of the encoded data stream.

The tree processor/encoder-decoder circuit 124 of Figures 31 and 32 comprises a CONTROL_COUNTER block 3124. CONTROL_COUNTER block 3214 controls overall timing and sequencing of the other blocks of the tree processor/encoder/decoder circuit 124 by outputting the control signals that determine the timing of the operations that these blocks perform. In accordance with one embodiment of the present invention, the tree processor/encoder/decoder 112 is fully pipelined in a nine stage pipeline sequence, each stage occupying one clock cycle. Appendix C illustrates an embodiment of CONTROL_COUNTER block 3124 described in VHDL code.

The signals output by CONTROL_COUNTER block 3124 comprise a read_enable signal on lead 3404, which is active during read cycles, and a write_enable signal on lead 3406, which is active during write cycles. The signals output also comprise memory control signals on leads 3108 and 3110, which control the old and new portions of memory unit 116, respectively, for reading from memory or writing to memory. The signals output also comprise a 4-bit state vector on lead 3138, which supplies MODE_CONTROL block 3118 with the current cycle. The four-bit state vector counts through values 1 through 4 during the "skip" cycle, the value 5 during the "token" cycle, and the values 6-9 during the "data" cycle. The signals output by CONTROL_COUNTER block 3124 also comprise a cycle state value on leads 3802, which signals buffer 3122 when a token cycle or data cycle is taking place.

Figure 42 illustrates a pipelined encoding/decoding process controlled by CONTROL_COUNTER block 3124. Cycles are divided into three types: data cycles - when Huffman encoded/decoded data is being output/input into the encoded bit stream and when old frame values are being written back to memory; token cycles - when a token is being output/input; and skip cycles - the remaining case when no encoded/decoded data is output to or received from the encoded bit stream. A counter in CONTROL_COUNTER block 3124 counts up to 8 then resets to 0. At each sequence of the count, this counter decodes various control signals depending on the current MODE. The pipeline cycles are:

- 0) read old[0][0] and in encode new[0][0]; skip cycle.
- 1) read old[1][0] and in encode new[1][0]; skip cycle.
- 2) read old[0][1] and in encode new[0][1]; skip cycle.
- 3) read old[1][1] and in encode new[1][1]; skip cycle.
- 4) DECIDE blocks outputs flags MODE_CONTROL write/read token into/from coded data stream: generates new_mode, outputs tokens in encode; generates new_mode, inputs tokens in decode; token cycle.

- 5) Huffman encode/decode qindex[0][0], and write old[0][0]; data cycle.
- 6) Huffman encode/decode qindex[1][0], and write old[1][0]; data cycle.
- 7) Huffman encode/decode qindex[0][1], and write old[0][1]; data cycle.
- 8) Huffman encode/decode qindex[1][1], and write old[1][1]; data cycle.

Figure 42 illustrates that once the new_mode is calculated, another block of data values in the tree can be processed. The tree processor/encoder/decoder is thus fully pipelined, and can process four new transformed data values every five clock cycles. To change the pipeline sequence, it is only required that the control signals in the block CONTROL_COUNTER block 3124 be reprogrammed.

ADDITIONAL EMBODIMENTS

5

10

In accordance with the above-described embodiments, digital video in 4:1:1 format is output from A/D video decoder 110 on lines 202 to the discrete wavelet transform circuit 122 of video encoder/decoder circuit 112 row by row in raster-scan form. Figure 43 illustrates another embodiment in accordance with the present invention. Analog video is supplied from video source 104 to an A/D video decoder circuit 4300. The A/D video decoder circuit 4300, which may, for example, be manufactured by Philips, outputs digital video in 4:2:2 format on lines 4301 to a horizontal decimeter circuit 4302. For each two data values input to the horizontal decimeter circuit 4302, the horizontal decimeter circuit 4302 performs low pass filtering and outputs one data value. The decimated and low pass filtered output of horizontal decimeter circuit 4302 is supplied to a memory unit 114 such that data values are written into and stored in memory unit 114 as illustrated in Figure 43. The digital video in 4:2:2 format on lines 4301 occurs at a frame rate of 30 frames per second, each frame consisting of two fields. By discarding the odd field, the full 33-3 ms frame period is available for transforming and compressing/decompressing the remaining even field. The even fields are low-pass filtered by the horizontal decimeter circuit 4302 occurs at a rate of 30 frames per second, each frame consisting of only one field. Memory unit 114 contains 640 x 240 total image data values. There are 320 x 240 Y data values, as well as 160 x 240 U data values, as well as 160 x 240 V data values.

In order to perform a forward transform, the Y values from memory unit 114 are read by video encoder/decoder chip 112 as described above and are processed by the row convolver and column convolver of the discrete wavelet transform circuit 122 such that a three octave sub-band decomposition of Y values is written into memory unit 116. The three octave sub-band decomposition for the Y values is illustrated in Figure 43 as being written into a Y portion 4303 of the new portion of memory unit 116.

After the three octave sub-band decomposition for the Y values has been written into memory unit 116, the video encoder/decoder chip 112 reads the U image data values from memory unit 114 but bypasses the row convolver. Accordingly, individual columns of U values in memory unit 114 are digitally filtered into low and high pass components by the column convolver. The high pass component G is discarded and the low pass component H is written into U portion 4304 of the new portion of memory unit 116 illustrated in Figure 43. After the U portion 4304 of memory unit 116 has been written with the low pass H component of the U values, video encoder/decoder chip 112 reads these U values from U portion 4304 and processes these U data values using both the row convolver and column convolver of the discrete wavelet transform circuit 122 to perform an additional two octaves of transform to generate a U value sub-band decomposition. The U value sub-band decomposition is stored in U portion 4304 of memory unit 116. Similarly, the V image data values in memory unit 114 are read by video encoder/decoder chip 112 into the column convolver of the discrete wavelet transform circuit 122, the high pass component G being discarded and the low pass component H being written into V portion 4305 of the new portion of memory unit 116. The V data values of V portion 4305 are then read by the video encoder/decoder chip 112 and processed by both the row convolver and the column convolver of discrete wavelet transform circuit 122 to generate a V sub-band decomposition corresponding to the U sub-band decomposition stored in U portion 4304. This process completes a forward three octave discrete wavelet transform comparable to the 4:1:1 three octave discrete wavelet transform described above in connection with Figures 3A-3C. Y portion 4303 of memory unit 116 comprises 320 x 240 data value memory locations; U portion 4304 comprises 160 x 120 data value memory locations; and V portion 4305 comprises 160 x 120 data value

The DWT address generator 508 illustrated in Figure 5 generates a sequence of 19-bit addresses on output lines OUT2. In accordance with the presently described embodiment, however, memory unit 114 is a dynamic random access memory (DRAM). This memory unit 114 is loaded from horizontal decimeter circuit 4302 and is either read from and written to by the video encoder/decoder chip 112. For example, in order for the video encoder/decoder chip 112 to access the Y data values in memory unit 114 the inc_R value supplied to DWT address generator 508 by control block 506 is set to 2. This causes the DWT address generator 508 of the video encoder/decoder chip 112 to increment through even addresses as illustrated in Figure 43 such that only

the Y values in memory unit 114 are read. After all the Y values are read from memory unit 114 and are transformed into a Y sub-band decomposition, then base_u_R is changed to 1 and the Channel_start_r is set so that BASE_MUX 3002 of Figure 30 selects the base_u_R to address the first U data value in memory unit 114. Subsequent U data values are accessed because the inc_R value is set to 4 such that only U data values in memory unit 114 are accessed. Similarly, the V data values are accessed by setting the base_v_R value to 3 and setting the Channel_start_r value such that BASE_MUX 3002 selects the base_v_R input leads. Successive V data values are read from memory unit 114 because the inc_R remains at 3.

Because in accordance with this embodiment the video encoder/decoder chip 112 reads memory unit 114, the DWT address generator 508 supplies both read addresses and write addresses to memory unit 114. The read address bus 3018 and the write address bus 3020 of Figure 30 are therefore multiplexed together (not shown) to supply the addresses on the OUT2 output lines of the DWT address generator.

To perform the inverse transform on a three octave sub-band decomposition stored in memory unit 116 of Figure 43, the row and column convolvers of the video encoder/decoder chip 112 require both low and high pass components to perform the inverse transform. When performing the octave 0 inverse transform on the U and V data values of the sub-band decomposition, zeros are inserted when the video encoder/decoder chip 112 is to read high pass transformed data values. In the octave 0 inverse transform, the row convolver is bypassed such that the output of the column convolver is written directly to the appropriate locations in the memory unit 114 for the U and V inverse transform data values. When the Y transform data values in memory unit 116 are to be inverse transformed, on the other hand, both the column convolver and the row convolver of the video encoder/decoder chip 112 are used on each of the three octaves of the inverse transform. The resulting inverse transformed Y data values are written into memory unit 114 in the appropriate locations as indicated in Figure 43.

Figure 44 illustrates a sequence of reading and writing Y data values from the Y portion of the new portion of memory unit 116 in accordance with the embodiment of the present invention illustrated in Figure 1 where memory unit 116 is a static random access memory (SRAM). The dots in Figure 44 represent individual memory locations in a two-dimensional matrix of memory locations adequately wide and deep to store an entire subband decomposition of the Y values in a single two-dimensional matrix. The discrete wavelet transform chip 122 reads the memory location indicated R0 during a first time period, outputs a transformed data value during a second time period to the memory location indicated W1, reads another data value from the memory location denoted R2, writes a transformed data value to the memory location denoted W3 and so forth. If memory unit 116 is realized as a dynamic random access memory (DRAM), addressing memory unit 116 in this manner results in a different row of the memory unit being accessed each successive time period. When successive accesses are made to different rows of standard dynamic random access memory, a row address select (RAS) cycle must be performed each time the row address changes. On the other hand, if successive accesses are performed on memory locations that fall in the same row, then only column address select (CAS) cycles need to be performed. Performing a CAS cycle is significantly faster in a standard dynamic random access memory than a RAS cycle. Accordingly, when memory unit 114 is realized as a dynamic random access memory and when memory unit 116 is read and written in the fashion illustrated in Figure 44, memory accesses are slow.

Figure 45 illustrates a sequence of reading and writing memory unit 116 in accordance with another embodiment of the present invention wherein memory unit 118 is realized as a dynamic random access memory. Again, the dots denote individual memory locations and the matrix of memory locations is assumed to be wide enough and deep enough to accommodate the Y portion of the sub-band decomposition in a single two-dimensional matrix. In the first time period, the memory location designated R0 is read. In the next time period, the memory location R1 is read, then R2 is read in a subsequent time period, then R3 is read in a subsequent period, and so forth. In this way one row of low pass component HH values is read into the video encoder/decoder chip 112 using only one RAS cycle and multiple CAS cycles. Then, a second row of low pass component HH data values is read as designated in Figure 45 by numerals R160, R161, R162 and so forth. The last low pass component data value to be read in the second row is designated R319. This row is also read into the video encoder/decoder chip 112 using only one RAS cycle and multiple CAS cycles. Figure 15 illustrates that after reading the data values that the resulting octave 1 transformed data values determined by the discrete wavelet transform chip 122 are now present in the line delays designated 1334 and 1340 illustrated in Figure 13. At this point in this embodiment of the present invention, the row convolver and the column convolver of the discrete wavelet transform chip 122 are stopped by freezing all the control signals except that line delays 1334 and 1340 are read in sequential fashion and written to the Y portion of the new portion of memory unit 116 as illustrated in Figure 45. In this fashion, two rows of memory locations which were previously read in time periods 0 through 319 are now overwritten with the resulting octave 1 transformed values in periods 320 through 639. Only one RAS cycle is required to write the transformed data values in time periods 320 through 479. Similarly, only one RAS cycle is required to write transformed data values during time periods 480 through 639. This results in significantly faster accessing of memory unit 116. Because dynamic random access memory can be used to realize memory unit 116 rather than static random access memory, system cost is reduced considerably.

In accordance with this embodiment of the present invention, the output of the output OUT2 of the column convolver of the video encoder/decoder circuit 112 is coupled to the output leads of block 1332 as illustrated in Figure 13. However, in the forward or inverse transform of any other octave, the output leads OUT2 are coupled to the line delay 1340. Accordingly, in an embodiment in accordance with the memory accessing scheme illustrated in Figure 45, a multiplexer (not shown) is provided to couple either the output of line delay 1340 or the output of adder block 1332 to the output leads OUT2 of the column wavelet transform circuit 704 of Figure 13

Figure 46 illustrates another embodiment in accordance with the present invention. Memory unit 116 contains a new portion and an old portion. Each of the new and old portions contains a sub-band decomposition. Due to the spatial locality of the wavelet sub-band decomposition, each two-by-two block of low pass component data values has a high pass component consisting of three trees of high frequency two-by-two blocks of data values. For example, in a three octave sub-band decomposition, each two-by-two block of low pass component data values and its associated three trees of high pass component data values forms a 16-by-16 area of memory which is illustrated in Figure 46.

In order for memory unit 116 to be realized in dynamic random access memory (DRAM), the static random access memories (SRAMs) 4600, 4601, 4602 and 4603 which are used as line delays in the discrete wavelet transform circuit 122 are used as cache memory to hold one 16-by-16 block in the new portion of memory unit 116 as well as one 16-by-16 block in the old portion of memory unit 116. This allows each 16-by-16 block of dynamic random access memory realizing the new and old portions of memory unit 116 to be accessed using at most sixteen RAS cycles. This allows the video encoder/decoder chip 112 to use dynamic random access memory for memory unit 116 rather than static random access memory, thereby reducing system cost.

Figure 47 illustrates a time line of a sequence of operations performed by the circuit illustrated in Figure 46. In a first time period, old 16-by-16 block 3 is read into SRAM 1 4601. Because there is only one set of data pins on video encoder/decoder chip 112 for accessing memory unit 116, the 16-by-16 block 0 of the new portion of memory unit 116 is read into SRAM 0 4600 in the second time period. Bidirectional multiplexer 4604 is controlled by select inputs 4605 to couple the 16-by-16 block of old data values now present in SRAM 1 4601 to the bidirectional input port old 4606 of the tree processor/ encoder/decoder circuit 124. Similarly, the 16-by-16 new data values present in SRAM 0 4600 are coupled to the input port new 4607 of the tree processor/encoder/ decoder circuit 124. Accordingly, the tree processor/ encoder/decoder circuit 124 performs tree processing and encoding in a third time period. During the same third time period, the inverse quantized old 16by-16 block is rewritten into SRAM 1 4601 through multiplexer 4604. In a fourth time period, old 16-by-16 block 2 is read into SRAM 2 4602. Subsequently, in the fifth time period a 16-by-16 block of new data values is read from memory unit 116 into SRAM 0 4600. The new and old 16-by-16 blocks are again provided to the tree processor/encoder/decoder for processing, the inverse quantized 16-by-16 old block being written into SRAM 2 4602. During the period of time when the tree processor/encoder/decoder circuit 124 is performing tree processing and encoding, the inverse quantized 16-by-16 block in SRAM 1 4801 is written back to 16-by-16 block 3 of the old portion of memory unit 116. Subsequently, in the seventh time period, 16-by-16 block 5 of the old portion of memory unit 116 is read into SRAM 1 4601 and in the eighth time period the 16-by-16 block of new data values 4 in memory unit 116 is read into SRAM 0 4600. In the ninth time period, tree processor/encoder/decoder circuit 124 processes the 16-by-16 new and old blocks 4 and 5 while the 16-by-16 block of inverse quantized data values in SRAM 2 4602 is written to 16-by-16 block 2 in the old portion of memory unit 116. This pipellning technique allows the dynamic random access memory (DRAM) to be accessed during each time period by taking advantage of the time period when the tree processor/encoder/decoder circuit 124 is processing and not reading from memory unit 116. Because all accesses of memory unit 116 are directed to 16by-18 blocks of memory locations, the number of CAS cycles is maximized. Arrows are provided in Figure 4 6 between memory unit 116 and video encoder/decoder circuit 112 to illustrate the accessing of various 16by-16 blocks of the new and old sub-band decompositions during different time periods. However, because video encoder/decoder chip 112 only has one set of data leads through which data values can be read from and written to memory unit 116, the input/output ports on the right sides of dual port static random access memories 4600-4602 are bussed together and coupled to the input/output data pins of the video encoder/decoder chip 112.

In order to avoid the necessity of providing an additional memory to realize first-in-first-out (FIFO) memory 120, SRAM 3 4603, which is used as a line delay in the column convolver of the video encoder/decoder chip 112, is coupled to the tree processor/encoder/decoder circuit 124 to buffer the compressed data stream for encoding and decoding operations between the ISA bus 106 and the video encoder/decoder chip 112. This

EP 0 622 741 A2

sharing of SRAM 3 is possible because the discrete wavelet transform circuit 122 operates in a first time period and the tree processor/encoder-decoder circuit 124 operates in a second time period.

When the tree processor/encoder/decoder circuit 124 is performing the decoding function, the new portion of memory unit 116 is not required and SRAM 0 is unused. The read 0, read 1, and read 4 time periods of the time line illustrated in Figure 47 are therefore omitted during decoding.

Although the present invention has been described by way of the above described specific embodiments, the invention is not limited thereto. Adaptations, modifications, rearrangements and combinations of various features of the specific embodiments may be practiced without departing from the scope of the invention. For example, an integrated circuit chip may be realized which performs compression but not decompression and another integrated circuit chip may be realized which performs decompression but not compression. Any level of integration may be practiced including placing memory units on the same chip with a discrete wavelet transform circuit and a tree processor/encoder-decoder circuit. The invention may be incorporated into consumer items including personal computers, video cassette recorders (VCRs), video cameras, televisions, compact disc (CD) players and/or recorders, and digital tape equipment. The invention may process still image data, video data and/or audio data. Filters other than four coefficient quasi-Daubechies forward transform filters and corresponding four coefficient reconstruction (inverse transform) filters may be used including filters disclosed in copending Patent Cooperation Treaty (PCT) application filed March 30, 1994, entitled "Data Compression and Decompression*. Various start and end forward transform filters and various corresponding start and end reconstruction (inverse transform) filters may also be used including filters disclosed in copending Patent Cooperation Treaty (PCT) application filed March 30, 1994, entitled "Data Compression and Decompression". Tokens may be encoded or unencoded. Other types of tokens for encoding other information including motion in consecutive video frames may be used. Other types of encoding other than Huffman encoding may be used and different quantization schemes may be employed. The above description of the preferred embodiments is therefore presented merely for illustrative instructional purposes and is not intended to limit the scope of the invention as set forth in the appended claims.

- 1. A method comprising the step of:
 - using a number of intercoupled accumulators, each accumulator comprising at least an adder circuit and a storage circuit, to filter a sequence of input image data values with both a first digital filter having X coefficients and a second digital filter having Y coefficients into a sequence of transformed image data values, Y being substantially equal to the number of intercoupled accumulators, wherein X < T.
- 2. A method as claimed in claim 1 wherein a first data value of the sequence of transformed image data values is an output of the first digital filter and wherein a second data value of the sequence of transformed image data values is an output of the second digital filter.
 - 3. A method as claimed in claim 1 or 2 wherein the first digital filter is a boundary filter.
 - 4. A method comprising the steps of:
 - multiplying a first data value of a sequence of data values by a first plurality of predetermined values to generate a first plurality of products;

inputting a selected one of the plurality of products into a first input of a first accumulator;

multiplying a second data value of the sequence of data values by a second plurality of predetermined values to generate a second plurality of products;

inputting a selected one of the second plurality of products into a first input of a second accumulators, an output of the first accumulator being supplied to a second input of the second accumulator.

multiplying a third data value of the sequence of data values by a third plurality of predetermined values to generate a third plurality of products;

inputting a selected one of the third plurality of products into a first input of a third accumulator, an output of the second accumulator being supplied to a second input of the third accumulator;

multiplying a fourth data value of the sequence of data values by at least one predetermined value to generate at least one fourth product; and

inputting the at least one fourth product into a first input of a fourth accumulator, an output of the third accumulator being supplied to a second input of the fourth accumulator, wherein each of the plurality of predetermined values is selected from coefficients of a quasi-perfect reconstruction filter and coefficients of a boundary quasi-perfect reconstruction filter.

- 5. A method as claimed in claim 4 wherein each of the first, second, third and fourth accumulators comprises at least an adder circuit and a storage circuit, each of the storage circuits storing a number A of partially transformed data values during processing of one octave of a decomposition, and each of the storage circuits storing a number B of partially transformed data values during processing of another octave of a decomposition, wherein A is not equal to B.
- 6. A method as claimed in claim 4 or 5 wherein the sequence of data values comprises data values of rows and columns of a two-dimensional image, the method transforming both the rows and the columns of data values into a sub-band decomposition.
- 7. A method comprising the steps of:

multiplying a first data value of a sequence of data values by a first plurality of predetermined values to generate a first plurality of products;

inputting a selected one of the plurality of products into a first input of a first accumulator; multiplying a second data value of the sequence of data values by a second plurality of predetermined values to generate a second plurality of products;

inputting a selected one of the second plurality of products into a first input of a second accumulator, an output of the first accumulator being supplied to a second input of the second accumulator;

multiplying a third data value of the sequence of data values by a third plurality of predetermined values to generate a third plurality of products;

inputting a selected one of the third plurality of products into a first input of a third accumulator, an output of the second input of the third accumulator;

multiplying a fourth data value of the sequence of data values by at least one predetermined value to generate at least one fourth product; and

inputting the at least one fourth products into a first input of a fourth accumulator, an output of the third accumulator being supplied to a second input of the fourth accumulator, wherein at least some of

the plurality of predetermined values are selected from coefficients of a boundary perfect reconstruction filter and coefficients of a boundary quasi-perfect reconstruction filter.

- A method as claimed in claim 7 wherein the output of the second accumulator is supplied to a second input of the first accumulator, wherein the output of the third accumulator is supplied to a third input of the second accumulator, and wherein the output of the fourth accumulator is supplied to a third input of the third accumulator.
- A method comprising the steps of:

multiplying a first data value of a sequence of data values by a first plurality of predetermined values to generate a first plurality of products;

inputting a selected one of the plurality of products into a first input of a first accumulator, the first accumulator having a first output terminal;

multiplying a second data value of the sequence of data values by a second plurality of predetermined values to generate a second plurality of products;

inputting a selected one of the second plurality of products into a first input of a second accumulator, an output of the first accumulator being supplied to a second input of the second accumulator, the output of the second accumulator being supplied to a second input of the first accumulator,

multiplying a third data value of the sequence of data values by a third plurality of predetermined values to generate a third plurality of products;

inputting a selected one of the third plurality of products into a first input of a third accumulator, an output of the second accumulator being supplied to a second input of the third accumulator, the output of the third accumulator being supplied to a third input of the second accumulator,

multiplying a fourth data value of the sequence of data values by at least one predetermine value to generate at least one fourth product; and

inputting the at least one fourth product into a first input of a fourth accumulator, an output of the third accumulator being supplied to a second input of said fourth accumulator, the output of the fourth accumulator being supplied to a third input of the third accumulator, the fourth accumulator having a second output terminal.

10. A method comprising the steps of:

reading a sequence of data values from a plurality of memory locations, each of the data values being stored in a separate one of the plurality of memory locations; and

overwriting some of the memory locations one at a time into a sequence of transformed data values of a sub-band decomposition.

- 11. A wavelet transform circuit arranged for transforming a sequence of a number C of input image data values adjacent an image boundary into a corresponding sequence of the number C of transformed image data values, the transformed image data values consisting of alternating low and high pass transformed image data values.
- 12. A wavelet transform circuit for transforming a sequence of data values adjacent a boundary of the data values, the sequence comprising a boundary subsequence adjacent the boundary and a non-boundary subsequence, the circuit comprising:
 - a multiplier circuit having an input for receiving an input data value and a plurality outputs;
 - a first multiplexer having a plurality of data inputs each coupled to selected ones of the plurality of outputs of the multiplier circuit, at least one control input, and a data output,
 - a first accumulator circuit having a first data input coupled to the data output of the first multiplexer, a second data input, a plurality of control inputs, and a data output,
 - a second multiplexer having a plurality of data inputs each coupled to selected ones of the plurality of outputs of the multiplier circuit, at least one control input, and a data output,
 - a second accumulator circuit having a first data input coupled to the data output of the second multiplexer, a second data input coupled to the data output of the first accumulator circuit, a third data input, a plurality of control inputs, and a data output,
 - a third multiplexer having a plurality of data inputs, at least one control input, and a data output;
 - a third accumulator circuit having a first data input coupled to the data output of the third multiplexer, a second data input coupled to the data output of the second accumulator circuit, a third data input, a plurality of control inputs, and a data output,

a fourth accumulator circuit having a first data input, a second data input coupled to one of the plurality of outputs of the multiplier circuit, a plurality of control inputs, and a data output coupled to the third data input of the third accumulator circuit, and

a control circuit coupled to the control inputs of the first, second and third multiplexers and the first, second, third and fourth accumulator circuits, the control circuit controlling the first, second, third multiplexers and the first, second, third and fourth accumulator circuits to transform the boundary subsequence using a first digital filter and to transform the non-boundary subsequence using a second digital filter.

13. A method of addressing selected ones of a plurality of memory locations, the plurality of memory locations storing a plurality of image data values, the method comprising the steps of:

5

15

20

25

30

35

40

45

50

55

addressing a sequence of a plurality of memory locations in a first period of time;

transforming at least some of the sequence into a first octave of sub-band decomposition during the first period of time;

addressing a subsequence of the sequence of the plurality of memory locations in a second period of time; and

transforming at least some of the subsequence from the first octave into a second octave during the second period of time, the first and second octaves comprising at least part of a sub-band decomposition.

- 14. A method as claimed in claim 13 wherein the step of addressing a sequence comprises adding one of a first value and a second value to a first address to generate a second address, the first and second addresses of the sequence being addresses of successive ones of the sequence of memory locations, and wherein the step of addressing a subsequence comprises the step of adding one of a third value and a fourth value to a first address of the subsequence of memory locations to generate a second address of the subsequence of memory locations, the first and second addresses of the subsequence being addresses of successive ones of the subsequence of memory locations.
 - 15. A method as claimed in claim 13 wherein the step of addressing a sequence comprises subtracting one of a first value and a second value from a first address to generate a second address, the first and second addresses of the sequence being addresses of successive ones of the sequence of memory locations, and wherein the step of addressing a subsequence comprises the step of subtracting one of a third value and a fourth value from a first address of the subsequence of memory locations to generate a second address of the subsequence of memory locations, the first and second addresses of the subsequence being addresses of successive ones of the subsequence of memory locations.
 - 16. A method of addressing selected ones of a plurality of memory locations storing a plurality of data values of a sub-band decomposition comprising a number of octaves, the method comprising the step of:

generating a second address by adding or by subtracting one of a first number and a second number to a first address, the first number having a value which is octave-dependent, the second number having another value which is octave-dependent, and the first and second addresses being successive addresses of respective ones of said plurality of memory locations.

- 17. A circuit for generating an address of a memory location of a plurality of memory locations storing a plurality of data values of a sub-band decomposition, the circuit comprising:
 - a first counter which increments by an octave-dependent first variable number of counts,
 - a multiplier circuit having a first data input coupled to an output of the first counter, a second data input coupled to receive a value indicative of a size of an image, and a data output,
 - a second counter which increments by an octave-dependent second variable number of counts, an adder circuit having a first data input coupled to the out-put of the multiplier circuit, a second data input coupled to an output of the second counter, and a data output on which the address is generated.
- 18. A circuit as claimed in claim 17 wherein the first counter receives a clock input signal and increments by the first variable number of counts in one clock cycle of the clock input signal, and wherein the second counter receives a clock input signal and increments by the second variable number of counts in one clock cycle of the clock input signal.
- 19. A state machine for generating an address of a memory location of a plurality of memory locations storing a plurality of data values of a sub-band decomposition, the data values comprising luminance data values,

the state machine receiving:

- a first signal upon which the state machine changes states,
- a second signal indicative of an octave of the sub-band decomposition, and
- a third signal indicative of a whether the address being generated is a luminance data value, the state machine changing state based upon the first, second, and third signals.
 - 20. A state machine as claimed in claim 19 wherein the state machine also receives a fourth signal indicative of a whether the address being generated is a chrominance data value, the state machine changing state based upon the fourth signal.
 - 21. A circuit for generating an address and comprising:

an accumulator circuit having a first data input for receiving a first increment value, a second data input for receiving a second increment value, a third data input, and a data output, said accumulator circuit, and

a storage element having a data input coupled to the data output of the accumulator circuit, and a data output coupled to the third data input of the accumulator circuit, the address being output on the data output of the storage element.

- 22. a circuit as claimed in claim 22 wherein the accumulator circuit has a fourth data input receiving an address base-offset chrominance value, and a fifth data input receiving an address base-offset luminance value.
- 23. A circuit comprising:

5

10

15

20

25

30

35

40

45

50

a flag generating circuit which receives a plurality of data values of a new block and a plurality of data values of an old block and generates a plurality of different flags, the new block being a block of a sub-band composition of a new frame, the old block being a block of a sub-band decomposition of an old frame, the different flags being selected from flags consisting of ORIGIN, NEW_Z, NO_Z, MOTION, NO-FLAG; and

a stage machine which assumes a given new state based on a current stage of the state machine and also on the different flags, the state machine outputting a token indicating the new state of the stage machine, the new stage being selected from VOID, SEND, STILL, SEND-STILL, STOP.

24. A method comprising the steps of:

using a digital circuit to low pass filter a first sequence of a first number of image data values into a second sequence of a second number of image values, the second number being less than the first number, and

using the digital circuit to low pass filter the second sequence of image data values to generate a sub-band decomposition.

- 25. A method as claimed in claim 24 wherein the digital circuit is a low pass forward transform perfect reconstruction digital filter.
- 26. A method as claimed in claim 26 wherein the digital circuit comprises a convolver.
- 27. A method comprising the steps of:

reading a number of first data values from a first number of rows of memory locations of a memory, the number of first data values comprising a part of a sub-band decomposition;

transforming or inverse transforming the number of first data values to generate a number of second data values, the number of second data values comprising high pass component data values and low pass component data values; and

after the transforming step, writing the number of second data values to a second number of rows of memory locations of the memory, the first number of rows being equal to the second number of rows.

- 28. A method as claimed in claim 28 wherein the rows of memory locations read in the reading step are different rows from the rows of memory locations written in the writing step or are the same rows of memory locations that are written in the writing step.
- 29. A method as claimed in claim 27 or 28 wherein the number of first data values equal the number of second data values.

- 30. A method as claimed in claim 27, 28 or 28 wherein the memory is a dynamic memory.
- 31. A method comprising the steps of:

10

15

20

25

30

45

50

55

reading a number of first image data values from a first number of twos of memory locations of a memory;

transforming the number of first data values to generate a number of second data values of a subband decomposition, the number of second data values comprising high pass component data values and low pass component data values; and

after the transforming step, writing the number of second data values to a second number of rows of memory locations of the memory, the first number of rows being equal to the second number of rows.

32. A method comprising the steps of:

reading a first block of low pass component data values and associated first high pass component trees of blocks of data values from a first plurality of dynamic memory locations, the first plurality of dynamic memory locations containing a plurality of blocks of low pass component data values, and each of the blocks of low pass component data values having three associated high pass component trees of blocks of data values,

writing the first block of low pass component data values and associated first high pass component trees of blocks of data values red from the first plurality of dynamic memory locations into a second memory;

reading a second block of low pass component data values and associated second high pass component trees of blocks of data values from a second plurality of dynamic memory locations, the second plurality of dynamic memory locations containing a plurality of blocks of low pass component data values, and each of the blocks of low pass component data values having three associated high pass component trees of blocks of data values.

writing the second block of low pass component data values and associated second high pass component trees of blocks of data values read from the second plurality of dynamic memory locations into a fourth memory, and

processing the data values written into the second and fourth memories to generate a compressed image data stream.

- 33. A method as claimed in claim 32 wherein the second memory is a plurality of static random access memory locations, and wherein the fourth memory is another plurality of static random access memory locations.
- 34. A method as claimed in claim 32 or 33 wherein the first block of low pass component data values and associated first high pass component trees of blocks of data values consist of 256 memory locations, and wherein the first block of low pass component data values and associated first high pass component trees of blocks of data values comprise a part of a three octave sub-band decomposition.
- 40 35. A method as claimed in claim 32, 33 or 34 wherein the processing step generates a third block of low pass component data values and associated third high pass component trees of blocks of data values, the method comprising the steps of:

writing the third block of low pass component data values and associated third high pass component trees of blocks of data values into the fourth memory;

reading a fourth block of low pass component data values and associated fourth high pass component trees of blocks of data values from the second plurality of dynamic memory locations, the dynamic memory locations from which the fourth block is read being different dynamic memory locations from the dynamic memory locations from which said second block was read; and

after the step of reading the fourth block, writing the third block of low pass component data values and associated third high pass component trees of blocks of data values into the second plurality of dynamic memory locations.

36. A method as claimed in claim 32, 33 or 34 wherein the processing step generates a third block of low pass component data values and associated third high pass component trees of blocks of data values, the method comprising the steps of:

writing the third block of low pass component data values and associated third high pass component trees of blocks of data values into the fourth memory, and

reading the third block of low pass component data values and associated third high pass compo-

nent trees of blocks of data values from the fourth memory and writing the third block of low pass component data values and associated third high pass component trees of blocks of data values into the second plurality of dynamic memory locations.

37. A method comprising the steps of:

5

10

15

20

25

30

35

40

45

reading a first block of low pass component data values and associated first high pass component trees of blocks of data values from a first plurality of dynamic memory locations, the first plurality of dynamic memory locations containing a plurality of blocks of low pass component data values, each of the blocks of low pass component data values having three associated high pass component trees of blocks of data values,

writing the first block of low pass component data values and associated first high pass component trees of blocks of data values into a second memory,

receiving an encoded data stream and using the encoded data stream to generate a second block of low pass component data values and associates second high pass component trees of blocks of data values:

writing the second block of low pass component data values and associated second high pass component trees of blocks of data values into the second memory; and

38. A method comprising the steps of:

during a first period of time, using a plurality of memory locations of static random access memory as a line delay in a convolver, and

during a second period of time, using the plurality of memory locations to store a block of low pass component data values and associated high pass component trees of blocks of data values.

39. A system comprising:

a first circuit which receives a input data stream and which generates quantized data stream and an inverse quantized data stream, the input data stream comprising tokens and transformed image data values, and

a second circuit which receives the quantized data stream and which generates an inverse quantized data stream and which generates an inverse quantized data stream, the inverse quantized data stream generated by the second circuit being identical to the inverse quantized data stream generated by the first circuit.

40. A system as claimed in claim 30 wherein the first circuit comprises:

means for generating a mode control signal from the input data stream,

quantizer means for receiving the transformed image data values of the input data stream and the mode control signal and for quantizing said transformed image data values into the quantized data stream using one of a first quantization method and a second quantization method depending on the mode control signal, the quantizer means also being for generating the inverse quantized data stream from the quantized data stream, and

means for generating a compressed data stream from the quantized data stream, wherein the second circuit comprises:

means for generating a mode control signal from the compressed data stream,

means for generating quantized data values from the compressed data stream, and

quantizer means for receiving said quantized data values of the compressed data stream and the mode control signal and for inverse quantizing the quantized data values into a data stream.

41. A circuit for generating an address for traversing a sub-band decomposition, the circuit comprising:

a first counter receiving a first count enable signal, and generating a first plurality of count output signals and a first carry out signal,

a second counter receiving a second count enable signal, and generating a second plurality of count output signals and a second carry out signal,

a third counter receiving a third count enable signal, and generating a third plurality of count output signals and a third carry out signal,

a fourth counter receiving a fourth count enable signal and generating a fourth plurality of counter output signals and a fourth carry out signal, and

means for receiving the first, second, third, and fourth carry out signals and for generating the first, second, third and fourth count enable signals, the first, second, third and fourth plurality of count output

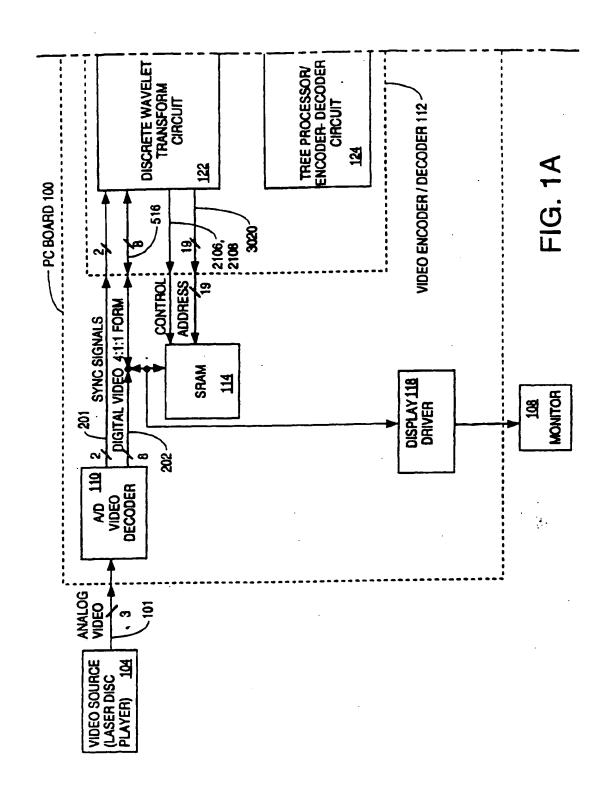

241

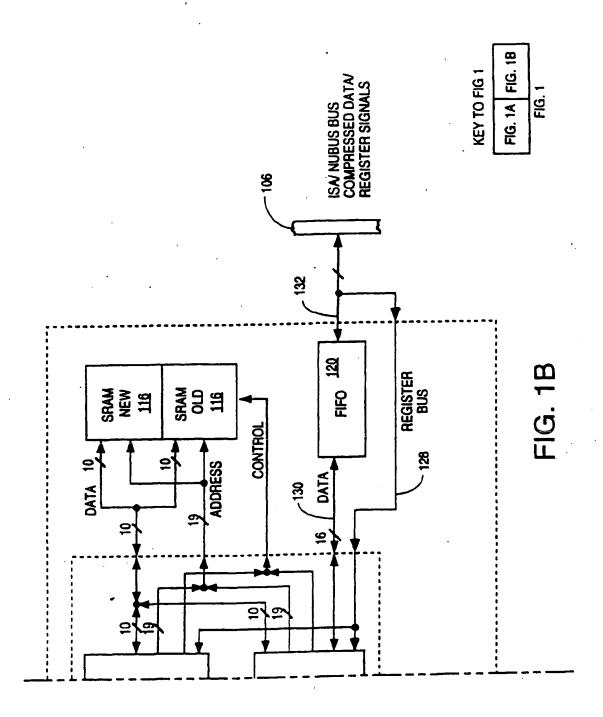

50

signals comprising the address.

42. A circuit as claimed in claim 41 wherein the sub-band decomposition comprises three high pass sub-bands, and wherein the first plurality of count output signals is indicative of an X address of a root of a tree, the second plurality of count output signals is indicative of a Y address of the root of the tree, the tree comprises a plurality of blocks of data values, the third plurality of count output signals is indicative of an address of data values in a block of data values of the tree, and the fourth plurality of counter output signals is indicative of the sub-band of the tree.
